Chapter 1

Introduction

Welcome to the RxODE user guide; **RxODE** is an R package for solving and simulating from ode-based models. These models are converted from the RxODE mini-language to C and create a compiled dll for fast solving. ODE solving using RxODE has a few key parts:

- `RxODE()` which creates the C code for fast ODE solving based on a simple syntax (Chapter 6) related to Leibnitz notation.
- The event data, which can be:
 - a `NONMEM` or `deSolve` compatible data frame (Chapter 7), or
 - created with `et()` or `EventTable()` for easy simulation of events (Chapter 11)
 - The data frame can be augmented by adding time varying or adding individual covariates (`iCov=` as needed)
- `rxSolve()` which solves the system of equations using initial conditions and parameters to make predictions
 - With multiple subject data, this may be parallelized.
 - With single subject the output data frame is adaptive
 - Covariances and other metrics of uncertainty can be used to simulate while solving.

While this is the user guide, there are other places that you can visit for help:

- RxODE github [pkgdown page](#)
- RxODE tutorial (accessible in Rstudio 1.3+)
- RxODE [github discussions](#)

This book was assembled on Tue Feb 23 22:40:00 2021 with RxODE version 1.0.4 automatically by github actions.

Chapter 2

Authors and Acknowledgments

2.1 Authors

- Matthew L. Fidler (core team/developer/manual)
- Melissa Hallow (tutorial writer)
- Wenping Wang (core team/developer)

2.2 Contributors

- Zufar Mulyukov – Wrote initial version of `rxShiny()` with modifications from Matthew Fidler
- Alan Hindmarsh – `Lsoda` author
- Awad H. Al-Mohy – Al-Mohy matrix exponential author
- Ernst Hairer – `dop853` author
- Gerhard Wanner – `dop853` author
- Goro Fuji – `Timsort` author
- Hadley Wickham – Author of original `findLhs` in `RxODE`, also original author of `.s3register` (used with permission to anyone, both changed by Matthew Fidler)
- Jack Dongarra – LAPack author; CRAN asked us to add
- Linda Petzold – `LSODA`
- Martin Maechler – `expm` author, used routines from there for inductive linearization
- Morwenn – `Timsort` author
- Nicholas J. Higham – Author of Al-mohy matrix exponential
- Roger B. Sidje – `expokit` matrix exponential author
- Simon Frost – thread safe C implementation of `liblsoda`
- Kevin Ushey – Original author of fast factor, modified by Matthew Fidler

- Yu Feng – thread safe liblsoda
- Matt Dowle – forder primary author (version modified by Matthew Fidler to allow different type of threading and exclude grouping)
- Cleve Moler – LAPack author; CRAN asked us to add
- David Cooley – Author of fast_factor which was modified and now is used RxODE to quickly create factors for IDs without sorting them like R does
- Daniel C. Dillon – Author of stripping utility to reduce size of RxODE/nlmixr executable
- Drew Schmidt – Drew Schmidt author of edits for exponential matrix utility taken from R package expm
- Arun Srinivasan – forder secondary author (version modified by Matthew Fidler to allow different type of threading, indexing and exclude grouping)

2.3 RxODE acknowledgments:

- Sherwin Sy – Weight based dosing example
- Justin Wilkins – Documentation updates, logo and testing
- Emma Schwager – R IJK distribution author
- J Coligne – dop853 fortran author
- Bill Denney – Documentation updates, manual and minor bug fixes
- Tim Waterhouse – Fixed one bug with mac working directories
- Richard Upton – Helped with solving the ADVAN linCmt() solutions
- Ross Ihaka – R author
- Robert Gentleman – R author
- R core team – R authors

Chapter 3

Related R packages

3.1 ODE solving

This is a brief comparison of pharmacometric ODE solving R packages to RxODE.

There are several [R packages for differential equations](#). The most popular is [deSolve](#).

However for pharmacometrics-specific ODE solving, there are only 2 packages other than [RxODE](#) released on CRAN. Each uses compiled code to have faster ODE solving.

- [mrgsolve](#), which uses C++ lsoda solver to solve ODE systems. The user is required to write hybrid R/C++ code to create a mrgsolve model which is translated to C++ for solving.

In contrast, RxODE has a R-like mini-language that is parsed into C code that solves the ODE system.

Unlike RxODE, [mrgsolve](#) does not currently support symbolic manipulation of ODE systems, like automatic Jacobian calculation or forward sensitivity calculation (RxODE currently supports this and this is the basis of [nlmixr](#)'s FOCEi algorithm)

- [dMod](#), which uses a unique syntax to create “reactions”. These reactions create the underlying ODEs and then created c code for a compiled [deSolve](#) model.

In contrast RxODE defines ODE systems at a lower level. RxODE's parsing of the mini-language comes from C, whereas dMod's parsing comes from R.

Like RxODE, dMod supports symbolic manipulation of ODE systems and calculates forward sensitivities and adjoint sensitivities of systems.

Unlike RxODE, dMod is not thread-safe since [deSolve](#) is not yet thread-safe.

And there is one package that is not released on CRAN:

- [PKPDsim](#) which defines models in an R-like syntax and converts the system to compiled code.

Like `mrgsolve`, `PKPDsim` does not currently support symbolic manipulation of ODE systems.

`PKPDsim` is not thread-safe.

The open pharmacometrics open source community is fairly friendly, and the Rx-ODE maintainers has had positive interactions with all of the ODE-solving pharmacometric projects listed.

3.2 PK Solved systems

RxODE supports 1-3 compartment models with gradients (using stan math's auto-differentiation). This currently uses the same equations as PKADVAN to allow time-varying covariates.

RxODE can mix ODEs and solved systems.

3.2.1 The following packages for solved PK systems are on CRAN

- [mrgsolve](#) currently has 1-2 compartment (poly-exponential models) models built-in. The solved systems and ODEs cannot currently be mixed.
- [pmxTools](#) currently have 1-3 compartment (super-positioning) models built-in. This is a R-only implementation.
- [PKPDmodels](#) has a one-compartment model with gradients.

3.2.2 Non-CRAN libraries:

- [PKADVAN](#) Provides 1-3 compartment models using non-superpositioning. This allows time-varying covariates.

Chapter 4

Installation

You can install the released version of RxODE from [CRAN](#) with:

```
install.packages("RxODE")
```

You can install the development version of RxODE with

```
devtools::install_github("nlmixrdevelopment/RxODE")
```

To build models with RxODE, you need a working c compiler. To use parallel threaded solving in RxODE, this c compiler needs to support open-mp.

You can check to see if R has working c compiler you can check with:

```
## install.packages("pkgbuild")  
pkgbuild::has_build_tools(debug = TRUE)
```

If you do not have the toolchain, you can set it up as described by the platform information below:

4.0.1 Windows

In windows you may simply use `installr` to install rtools:

```
install.packages("installr")  
library(installr)  
install.rtools()
```

Alternatively you can [download](#) and install rtools directly.

4.0.2 Mac OSX

To get the most speed you need OpenMP enabled and compile RxODE with that compiler. There are various options and the most up to date discussion about this is likely the [data.table installation faq for MacOS](#). The last thing to keep in mind is that RxODE uses the code very similar to the original lsoda which requires the gfortran compiler to be setup as well as the OpenMP compilers.

4.0.3 Linux

To install on linux make sure you install gcc (with openmp support) and gfortran using your distribution's package manager.

4.1 Development Version

Since the development version of RxODE uses StanHeaders, you will need to make sure your compiler is setup to support C++14, as described in the [rstan setup page](#). For R 4.0, I do not believe this requires modifying the windows toolchain any longer (so it is much easier to setup).

Once the C++ toolchain is setup appropriately, you can install the development version from [GitHub](#) with:

```
# install.packages("devtools")
devtools::install_github("nlmixrdevelopment/RxODE")
```

Chapter 5

Getting Started

The model equations can be specified through a text string, a model file or an R expression. Both differential and algebraic equations are permitted. Differential equations are specified by $d/dt(\text{var_name}) =$. Each equation can be separated by a semicolon.

To load RxODE package and compile the model:

```
library(RxODE)
```

```
#> RxODE 1.0.4 using 4 threads (see ?getRxThreads)
```

```
library(units)
```

```
#> udunits system database from /usr/share/xml/udunits
```

```
mod1 <-RxODE({  
  C2 = centr/V2;  
  C3 = peri/V3;  
  d/dt(depot) =-KA*depot;  
  d/dt(centr) = KA*depot - CL*C2 - Q*C2 + Q*C3;  
  d/dt(peri) = Q*C2 - Q*C3;  
  d/dt(eff) = Kin - Kout*(1-C2/(EC50+C2))*eff;  
})
```

```
#> qs v0.23.6.
```

5.1 Specify ODE parameters and initial conditions

Model parameters can be defined as named vectors. Names of parameters in the vector must be a superset of parameters in the ODE model, and the order of parameters within the vector is not important.

```
theta <-
  c(KA=2.94E-01, CL=1.86E+01, V2=4.02E+01, # central
    Q=1.05E+01, V3=2.97E+02,             # peripheral
    Kin=1, Kout=1, EC50=200)             # effects
```

Initial conditions (ICs) can be defined through a vector as well. If the elements are not specified, the initial condition for the compartment is assumed to be zero.

```
inits <- c(eff=1);
```

If you want to specify the initial conditions in the model you can add:

```
eff(0) = 1
```

5.2 Specify Dosing and sampling in RxODE

RxODE provides a simple and very flexible way to specify dosing and sampling through functions that generate an event table. First, an empty event table is generated through the “eventTable()” function:

```
ev <- eventTable(amount.units='mg', time.units='hours')
```

Next, use the `add.dosing()` and `add.sampling()` functions of the `EventTable` object to specify the dosing (amounts, frequency and/or times, etc.) and observation times at which to sample the state of the system. These functions can be called multiple times to specify more complex dosing or sampling regimens. Here, these functions are used to specify 10mg BID dosing for 5 days, followed by 20mg QD dosing for 5 days:

```
ev$add.dosing(dose=10000, nbr.doses=10, dosing.interval=12)
ev$add.dosing(dose=20000, nbr.doses=5, start.time=120,
              dosing.interval=24)
ev$add.sampling(0:240)
```

If you wish you can also do this with the `mattigr` pipe operator `%>%`

```
ev <- eventTable(amount.units="mg", time.units="hours") %>%
  add.dosing(dose=10000, nbr.doses=10, dosing.interval=12) %>%
  add.dosing(dose=20000, nbr.doses=5, start.time=120,
            dosing.interval=24) %>%
  add.sampling(0:240)
```

The functions `get.dosing()` and `get.sampling()` can be used to retrieve information from the event table.

```
head(ev$get.dosing())
```

```
#>   id low time high      cmt  amt rate ii addl evid ss dur
#> 1  1  NA    0   NA (default) 10000    0 12   9   1  0  0
#> 2  1  NA  120   NA (default) 20000    0 24   4   1  0  0
```

```
head(ev$get.sampling())
```

```
#>   id low time high      cmt amt rate ii addl evid ss dur
#> 1  1  NA    0   NA (obs)  NA  NA NA  NA    0 NA  NA
#> 2  1  NA    1   NA (obs)  NA  NA NA  NA    0 NA  NA
#> 3  1  NA    2   NA (obs)  NA  NA NA  NA    0 NA  NA
#> 4  1  NA    3   NA (obs)  NA  NA NA  NA    0 NA  NA
#> 5  1  NA    4   NA (obs)  NA  NA NA  NA    0 NA  NA
#> 6  1  NA    5   NA (obs)  NA  NA NA  NA    0 NA  NA
```

You may notice that these are similar to NONMEM event tables; If you are more familiar with NONMEM data and events you could use them directly with the event table function `et`

```
ev <- et(amountUnits="mg", timeUnits="hours") %>%
  et(amt=10000, addl=9, ii=12, cmt="depot") %>%
  et(time=120, amt=2000, addl=4, ii=14, cmt="depot") %>%
  et(0:240) # Add sampling
```

You can see from the above code, you can dose to the compartment named in the RxODE model. This slight deviation from NONMEM can reduce the need for compartment renumbering.

These events can also be combined and expanded (to multi-subject events and complex regimens) with `rbind`, `c`, `seq`, and `rep`. For more information about creating complex dosing regimens using RxODE see the [RxODE events section](#).

5.3 Solving ODEs

The ODE can now be solved by calling the model object's `run` or `solve` function. Simulation results for all variables in the model are stored in the output matrix `x`.

```
x <- mod1$solve(theta, ev, inits);
knitr::kable(head(x))
```

time	C2	C3	depot	centr	peri	eff
0	0.00000	0.0000000	10000.000	0.000	0.0000	1.000000
1	44.37555	0.9198298	7452.765	1783.897	273.1895	1.084664
2	54.88296	2.6729825	5554.370	2206.295	793.8758	1.180825
3	51.90343	4.4564927	4139.542	2086.518	1323.5783	1.228914
4	44.49738	5.9807076	3085.103	1788.795	1776.2702	1.234610
5	36.48434	7.1774981	2299.255	1466.670	2131.7169	1.214742

You can also solve this and create a RxODE data frame:

```
x <- mod1 %>% rxSolve(theta, ev, inits);
x
```

```
#> ----- Solved RxODE object -----
#> -- Parameters (x$params): -----
#>      V2      V3      KA      CL      Q      Kin      Kout      EC50
#> 40.200 297.000 0.294 18.600 10.500 1.000 1.000 200.000
#> -- Initial Conditions (x$inits): -----
#> depot centr peri eff
#>    0    0    0    1
#> -- First part of data (object): -----
#> # A tibble: 241 x 7
#>   time      C2      C3 depot centr peri eff
#>   [h] <dbl> <dbl> <dbl> <dbl> <dbl> <dbl>
#> 1     0     0     0 10000     0     0     1
#> 2     1  44.4  0.920  7453. 1784.  273.  1.08
#> 3     2  54.9  2.67  5554. 2206.  794.  1.18
#> 4     3  51.9  4.46  4140. 2087. 1324.  1.23
#> 5     4  44.5  5.98  3085. 1789. 1776.  1.23
#> 6     5  36.5  7.18  2299. 1467. 2132.  1.21
#> # ... with 235 more rows
#> -----
```

This returns a modified data frame. You can see the compartment values in the plot below:

```
library(ggplot2)
plot(x,C2) + ylab("Central Concentration")
```

Or,

```
plot(x,eff) + ylab("Effect")
```

Note that the labels are automatically labeled with the units from the initial event table. RxODE extracts `units` to label the plot (if they are present).

Chapter 6

RxODE syntax

This briefly describes the syntax used to define models that RxODE will translate into R-callable compiled code. It also describes the communication of variables between R and the RxODE modeling specification.

6.1 Example

```
# An RxODE model specification (this line is a comment).

if(comed==0){ # concomitant medication (con-med)?
  F = 1.0;    # full bioavailability w.o. con-med
}
else {
  F = 0.80;   # 20% reduced bioavailability
}

C2 = centr/V2; # concentration in the central compartment
C3 = peri/V3;  # concentration in the peripheral compartment

# ODE describing the PK and PD

d/dt(depot) = -KA*depot;
d/dt(centr) = F*KA*depot - CL*C2 - Q*C2 + Q*C3;
d/dt(peri)  = Q*C2 - Q*C3;
d/dt(eff)   = Kin - Kout*(1-C2/(EC50+C2))*eff;
```

6.2 Syntax

An RxODE model specification consists of one or more statements optionally terminated by semi-colons ; and optional comments (comments are delimited by # and an end-of-line).

A block of statements is a set of statements delimited by curly braces, { ... }.

Statements can be either assignments, conditional if/else if/else, while loops (can be exited by break), special statements, or printing statements (for debugging/testing)

Assignment statements can be:

- **simple** assignments, where the left hand is an identifier (i.e., variable)
- special **time-derivative** assignments, where the left hand specifies the change of the amount in the corresponding state variable (compartment) with respect to time e.g., $d/dt(\text{depot})$:
- special **initial-condition** assignments where the left hand specifies the compartment of the initial condition being specified, e.g. $\text{depot}(0) = 0$
- special model event changes including **bioavailability** ($f(\text{depot})=1$), **lag time** ($\text{alag}(\text{depot})=0$), **modeled rate** ($\text{rate}(\text{depot})=2$) and **modeled duration** ($\text{dur}(\text{depot})=2$). An example of these model features and the event specification for the modeled infusions the RxODE data specification is found in [RxODE events section](#).
- special **change point syntax, or model times**. These model times are specified by $\text{mtime}(\text{var})=\text{time}$
- special **Jacobian-derivative** assignments, where the left hand specifies the change in the compartment ode with respect to a variable. For example, if $d/dt(y) = dy$, then a Jacobian for this compartment can be specified as $df(y)/dy(dy) = 1$. There may be some advantage to obtaining the solution or specifying the Jacobian for very stiff ODE systems. However, for the few stiff systems we tried with LSODA, this actually slightly slowed down the solving.

Note that assignment can be done by =, <- or ~.

When assigning with the ~ operator, the **simple assignments** and **time-derivative** assignments will not be output.

Special statements can be:

- **Compartment declaration statements**, which can change the default dosing compartment and the assumed compartment number(s) as well as add extra compartment names at the end (useful for multiple-endpoint nlmixr models); These are specified by `cmt(compartmentName)`

- **Parameter declaration statements**, which can make sure the input parameters are in a certain order instead of ordering the parameters by the order they are parsed. This is useful for keeping the parameter order the same when using 2 different ODE models. These are specified by `param(par1, par2, ...)`

An example model is shown below:

```
# simple assignment
C2 = centr/V2;

# time-derivative assignment
d/dt(centr) = F*Ka*depot - CL*C2 - Q*C2 + Q*C3;
```

Expressions in assignment and if statements can be numeric or logical, however, no character nor integer expressions are currently supported.

Numeric expressions can include the following numeric operators `+`, `-`, `*`, `/`, `^` and those mathematical functions defined in the C or the R math libraries (e.g., `fabs`, `exp`, `log`, `sin`, `abs`).

You may also access the R's functions in the [R math libraries](#), like `lgammafn` for the log gamma function.

The RxODE syntax is case-sensitive, i.e., ABC is different than abc, Abc, ABc, etc.

6.2.1 Identifiers

Like R, Identifiers (variable names) may consist of one or more alphanumeric, underscore `_` or period `.` characters, but the first character cannot be a digit or underscore `_`.

Identifiers in a model specification can refer to:

- State variables in the dynamic system (e.g., compartments in a pharmacokinetics model).
- Implied input variable, `t` (time), `tlast` (last time point), and `podo` (oral dose, in the undocumented case of absorption transit models).
- Special constants like `pi` or [R's predefined constants](#).
- Model parameters (e.g., `ka` rate of absorption, `CL` clearance, etc.)
- Others, as created by assignments as part of the model specification; these are referred as *LHS* (left-hand side) variable.

Currently, the RxODE modeling language only recognizes system state variables and “parameters”, thus, any values that need to be passed from R to the ODE model (e.g., age) should be either passed in the `params` argument of the integrator function `rxSolve()` or be in the supplied event data-set.

There are certain variable names that are in the RxODE event tables. To avoid confusion, the following event table-related items cannot be assigned, or used as a state but can be accessed in the RxODE code:

- `cmt`
- `dvid`
- `addl`
- `ss`
- `rate`
- `id`

However the following variables are cannot be used in a model specification:

- `evid`
- `ii`

Sometimes RxODE generates variables that are fed back to RxODE. Similarly, `nlmixr` generates some variables that are used in `nlmixr` estimation and simulation. These variables start with the either the `rx` or `nlmixr` prefixes. To avoid any problems, it is suggested to not use these variables starting with either the `rx` or `nlmixr` prefixes.

6.3 Logical Operators

Logical operators support the standard R operators `==`, `!=`, `>=`, `<=`, `>` and `<`. Like R these can be in `if()` or `while()` statements, `ifelse()` expressions. Additionally they can be in a standard assignment. For instance, the following is valid:

```
cov1 = covm*(sexf == "female") + covm*(sexf != "female")
```

Notice that you can also use character expressions in comparisons. This convenience comes at a cost since character comparisons are slower than numeric expressions. Unlike R, `as.numeric` or `as.integer` for these logical statements is not only not needed, but will cause a syntax error if you try to use the function.

6.4 `cmt()` changing compartment numbers for states

The compartment order can be changed with the `cmt()` syntax in the model. To understand what the `cmt()` can do you need to understand how RxODE numbers the compartments.

Below is an example of how RxODE numbers compartments

6.4.1 How RxODE numbers compartments

RxODE automatically assigns compartment numbers when parsing. For example, with the Mavoglurant PBPK model the following model may be used:

```
library(RxODE)
pbpk <- RxODE({
  KbBR = exp(1KbBR)
  KbMU = exp(1KbMU)
  KbAD = exp(1KbAD)
  CLint= exp(1CLint + eta.LClint)
  KbBO = exp(1KbBO)
  KbRB = exp(1KbRB)

  ## Regional blood flows
  # Cardiac output (L/h) from White et al (1968)
  CO = (187.00*WT^0.81)*60/1000;
  QHT = 4.0 *CO/100;
  QBR = 12.0*CO/100;
  QMU = 17.0*CO/100;
  QAD = 5.0 *CO/100;
  QSK = 5.0 *CO/100;
  QSP = 3.0 *CO/100;
  QPA = 1.0 *CO/100;
  QLI = 25.5*CO/100;
  QST = 1.0 *CO/100;
  QGU = 14.0*CO/100;
  # Hepatic artery blood flow
  QHA = QLI - (QSP + QPA + QST + QGU);
  QBO = 5.0 *CO/100;

#> d/dt(Rest_of_Body) = QRB * (Arterial_Blood/VAB - Rest_of_Body/KbRB/VRB)
#> })
#> -----
```

In this case, Venous_Blood is assigned to compartment 15. Figuring this out can be inconvenient and also lead to re-numbering compartment in simulation or estimation datasets. While it is easy and probably clearer to specify the [compartment by name](#), other tools only support compartment numbers. Therefore, having a way to number compartment easily can lead to less data modification between multiple tools.

6.4.2 Changing compartments by pre-declaring with cmt()

To add the compartments to the RxODE model in the order you desire you simply need to pre-declare the compartments with `cmt`. For example specifying Venous_Blood and Skin to be the 1st and 2nd compartments, respectively, is simple:

```
pbpk2 <- RxODE({
  ## Now this is the first compartment, ie cmt=1
  cmt(Venous_Blood)
  ## Skin may be a compartment you wish to dose to as well,
  ## so it is now cmt=2
  cmt(Skin)
  KbBR = exp(1KbBR)
  KbMU = exp(1KbMU)
  KbAD = exp(1KbAD)
  CLint= exp(1CLint + eta.LCLint)
  KbBO = exp(1KbBO)
  KbRB = exp(1KbRB)

  ## Regional blood flows
  # Cardiac output (L/h) from White et al (1968)m
  CO = (187.00*WT^0.81)*60/1000;
  QHT = 4.0 *CO/100;
  QBR = 12.0*CO/100;
  QMU = 17.0*CO/100;
  QAD = 5.0 *CO/100;
```

```

QSK = 5.0 *CO/100;
QSP = 3.0 *CO/100;
QPA = 1.0 *CO/100;
QLI = 25.5*CO/100;
QST = 1.0 *CO/100;
QGU = 14.0*CO/100;
QHA = QLI - (QSP + QPA + QST + QGU); # Hepatic artery blood flow
QBO = 5.0 *CO/100;
QKI = 19.0*CO/100;
QRB = CO - (QHT + QBR + QMU + QAD + QSK + QLI + QBO + QKI);
QLU = QHT + QBR + QMU + QAD + QSK + QLI + QBO + QKI + QRB;

## Organs' volumes = organs' weights / organs' density
VLU = (0.76 *WT/100)/1.051;
VHT = (0.47 *WT/100)/1.030;
VBR = (2.00 *WT/100)/1.036;
VMU = (40.00*WT/100)/1.041;
VAD = (21.42*WT/100)/0.916;
VSK = (3.71 *WT/100)/1.116;
VSP = (0.26 *WT/100)/1.054;
VPA = (0.14 *WT/100)/1.045;
VLI = (2.57 *WT/100)/1.040;
VST = (0.21 *WT/100)/1.050;
VGU = (1.44 *WT/100)/1.043;
VBO = (14.29*WT/100)/1.990;
VKI = (0.44 *WT/100)/1.050;
VAB = (2.81 *WT/100)/1.040;
VVB = (5.62 *WT/100)/1.040;
VRB = (3.86 *WT/100)/1.040;

## Fixed parameters
BP = 0.61;      # Blood:plasma partition coefficient
fup = 0.028;    # Fraction unbound in plasma
fub = fup/BP;   # Fraction unbound in blood

KbLU = exp(0.8334);
KbHT = exp(1.1205);
KbSK = exp(-.5238);
KbSP = exp(0.3224);
KbPA = exp(0.3224);
KbLI = exp(1.7604);
KbST = exp(0.3224);
KbGU = exp(1.2026);
KbKI = exp(1.3171);

```

```
##-----
S15 = VVB*BP/1000;
C15 = Venous_Blood/S15

##-----
d/dt(Lungs) = QLU*(Venous_Blood/VVB - Lungs/KbLU/VLU);
d/dt(Heart) = QHT*(Arterial_Blood/VAB - Heart/KbHT/VHT);
d/dt(Brain) = QBR*(Arterial_Blood/VAB - Brain/KbBR/VBR);
d/dt(Muscles) = QMU*(Arterial_Blood/VAB - Muscles/KbMU/VMU);
d/dt(Adipose) = QAD*(Arterial_Blood/VAB - Adipose/KbAD/VAD);
d/dt(Skin) = QSK*(Arterial_Blood/VAB - Skin/KbSK/VSK);
d/dt(Spleen) = QSP*(Arterial_Blood/VAB - Spleen/KbSP/VSP);
d/dt(Pancreas) = QPA*(Arterial_Blood/VAB - Pancreas/KbPA/VPA);
d/dt(Liver) = QHA*Arterial_Blood/VAB + QSP*Spleen/KbSP/VSP +
  QPA*Pancreas/KbPA/VPA + QST*Stomach/KbST/VST + QGU*Gut/KbGU/VGU -
  CLint*fub*Liver/KbLI/VLI - QLI*Liver/KbLI/VLI;
d/dt(Stomach) = QST*(Arterial_Blood/VAB - Stomach/KbST/VST);
d/dt(Gut) = QGU*(Arterial_Blood/VAB - Gut/KbGU/VGU);
d/dt(Bones) = QBO*(Arterial_Blood/VAB - Bones/KbBO/VBO);
d/dt(Kidneys) = QKI*(Arterial_Blood/VAB - Kidneys/KbKI/VKI);
d/dt(Arterial_Blood) = QLU*(Lungs/KbLU/VLU - Arterial_Blood/VAB);
d/dt(Venous_Blood) = QHT*Heart/KbHT/VHT + QBR*Brain/KbBR/VBR +
  QMU*Muscles/KbMU/VMU + QAD*Adipose/KbAD/VAD + QSK*Skin/KbSK/VSK +
  QLI*Liver/KbLI/VLI + QBO*Bones/KbBO/VBO + QKI*Kidneys/KbKI/VKI +
  QRB*Rest_of_Body/KbRB/VRB - QLU*Venous_Blood/VVB;
d/dt(Rest_of_Body) = QRB*(Arterial_Blood/VAB - Rest_of_Body/KbRB/VRB);
})
```

You can see this change in the simple printout

```
pbpk2
```

```
#> RxODE 1.0.4 model named rx_1ba4e3e59709f3823846d20a74a04bf1 model (ready).
#> x$state: Venous_Blood, Skin, Lungs, Heart, Brain, Muscles, Adipose, Spleen, Pancreas, Liver, S
#> x$params: 1KbBR, 1KbMU, 1KbAD, 1CLint, eta.LClint, 1KbBO, 1KbRB, WT, BP, fup
#> x$lhs: KbBR, KbMU, KbAD, CLint, KbBO, KbRB, CO, QHT, QBR, QMU, QAD, QSK, QSP, QPA, QLI, QST, Q
```

The first two compartments are Venous_Blood followed by Skin.

6.4.3 Appending compartments to the model with cmt()

You can also append “compartments” to the model. Because of the ODE solving internals, you cannot add fake compartments to the model until after all the differential equations are defined.

For example this is legal:

```
ode.1c.ka <- RxODE({  
  C2 = center/V;  
  d / dt(depot) = -KA * depot  
  d/dt(center) = KA * depot - CL*C2  
  cmt(eff);  
})  
print(ode.1c.ka)
```

```
#> RxODE 1.0.4 model named rx_d7b072a8a056bc2b5099d6746c378590 model (ready).  
#> $state: depot, center  
#> $stateExtra: eff  
#> $params: V, KA, CL  
#> $lhs: C2
```

But compartments defined before all the differential equations is not supported;
So the model below:

```
ode.1c.ka <- RxODE({  
  cmt(eff);  
  C2 = center/V;  
  d / dt(depot) = -KA * depot  
  d/dt(center) = KA * depot - CL*C2  
})
```

will give an error:

```
Error in rxModelVars_(obj) :  
  Evaluation error: Compartment 'eff' needs differential equations defined.
```

Chapter 7

RxODE events

7.1 RxODE event tables

In general, RxODE event tables follow NONMEM dataset convention with the exceptions:

- The compartment data item (`cmt`) can be a string/factor with compartment names
 - You may turn off a compartment with a negative compartment number or “-`cmt`” where `cmt` is the compartment name.
 - The compartment data item (`cmt`) can still be a number, the number of the compartment is defined by the appearance of the compartment name in the model. This can be tedious to count, so you can specify compartment numbers easier by using the `cmt (cmtName)` at the beginning of the model.
- An additional column, `dur` can specify the duration of infusions;
 - Bioavailability changes will change the rate of infusion since `dur/amt` are fixed in the input data.
 - Similarly, when specifying `rate/amt` for an infusion, the bioavailability will change the infusion duration since `rate/amt` are fixed in the input data.
- Some infrequent NONMEM columns are not supported: `pcmt`, `call`.
- Additional events are supported:
 - `evid=5` or replace event; This replaces the value of a compartment with the value specified in the `amt` column. This is equivalent to `deSolve=replace`.

- `evid=6` or multiply event; This multiplies the value in the compartment with the value specified by the `amt` column. This is equivalent to `deSolve=multiply`.

Here are the legal entries to a data table:

Data Item	Meaning	Notes
<code>id</code>	Individual identifier	Can be a integer, factor, character, or numeric
<code>time</code>	Individual time	Numeric for each time.
<code>amt</code>	dose amount	Positive for doses zero/NA for observations
<code>rate</code>	infusion rate	When specified the infusion duration will be $\text{dur}=\text{amt}/\text{rate}$
<code>dur</code>	infusion duration	$\text{rate} = -1$, rate modeled; $\text{rate} = -2$, duration modeled
<code>evid</code>	event ID	When specified the infusion rate will be $\text{rate} = \text{amt}/\text{dur}$
<code>cmt</code>	Compartment	0=Observation; 1=Dose; 2=Other; 3=Reset; 4=Reset+Dose; 5=Replace; 6=Multiply
<code>ss</code>	Steady State Flag	Represents compartment #/name for dose/observation
<code>ii</code>	Inter-dose Interval	0 = non-steady-state; 1=steady state; 2=steady state +prior states
<code>addl</code>	# of additional doses	Time between doses.
		Number of doses like the current dose.

Other notes:

- The `evid` can be the classic RxODE (described [here](#)) or the NONMEM-style `evid` described above.
- NONMEM's DV is not required; RxODE is a ODE solving framework.
- NONMEM's MDV is not required, since it is captured in EVID.
- Instead of NONMEM-compatible data, it can accept `deSolve` compatible data-frames.

When returning the RxODE solved data-set there are a few additional event ids (EVID) that you may see depending on the solving options:

- EVID = -1 is when a modeled rate ends (corresponds to `rate = -1`)
- EVID = -2 is when a modeled duration ends (corresponds to `rate=-2`)
- EVID = -10 when a rate specified zero-order infusion ends (corresponds to `rate > 0`)

- EVID = -20 when a duration specified zero-order infusion ends (corresponds to $\text{dur} > 0$)
- EVID = 101, 102, 103, ... These correspond to the 1, 2, 3, ... modeled time (mtime).

These can only be accessed when solving with the option combination `addDosing=TRUE` and `subsetNonmem=FALSE`. If you want to see the classic EVID equivalents you can use `addDosing=NA`.

To illustrate the event types we will use the model from the original RxODE tutorial.

```
library(RxODE)
### Model from RxODE tutorial
m1 <- RxODE({
  KA=2.94E-01;
  CL=1.86E+01;
  V2=4.02E+01;
  Q=1.05E+01;
  V3=2.97E+02;
  Kin=1;
  Kout=1;
  EC50=200;
  ## Added modeled bioavailability, duration and rate
  fdepot = 1;
  durDepot = 8;
  rateDepot = 1250;
  C2 = centr/V2;
  C3 = peri/V3;
  d/dt(depot) = -KA*depot;
  f(depot) = fdepot
  dur(depot) = durDepot
  rate(depot) = rateDepot
  d/dt(centr) = KA*depot - CL*C2 - Q*C2 + Q*C3;
  d/dt(peri) = Q*C2 - Q*C3;
  d/dt(eff) = Kin - Kout*(1-C2/(EC50+C2))*eff;
  eff(0) = 1
});
```

7.2 Bolus/Additive Doses

A bolus dose is the default type of dose in RxODE and only requires the `amt/dose`. Note that this uses the convenience function `et()` described in the [RxODE event tables](#)

```
ev <- et(timeUnits="hr") %>%
  et(amt=10000, ii=12, until=24) %>%
  et(seq(0, 24, length.out=100))

ev
```

```
#> ----- EventTable with 101 records -----

#> 10 1.9393939    NA    NA    NA 0:Observation
#> # ... with 91 more rows
```

```
rxSolve(m1, ev) %>% plot(C2) +
  xlab("Time")
```

7.3 Infusion Doses

There are a few different type of infusions that RxODE supports:

- Constant Rate Infusion (rate)
- Constant Duration Infusion (dur)
- Estimated Rate of Infusion
- Estimated Duration of Infusion

7.3.1 Constant Infusion (in terms of duration and rate)

The next type of event is an infusion; There are two ways to specify an infusion; The first is the dur keyword.

An example of this is:

```
ev <- et(timeUnits="hr") %>%  
  et(amt=10000, ii=12, until=24, dur=8) %>%  
  et(seq(0, 24, length.out=100))  
ev
```

```
#> ----- EventTable with 101 records -----
#>
#> 1 dosing records (see x$get.dosing(); add with add.dosing or et)
#> 100 observation times (see x$get.sampling(); add with add.sampling or et)
#> multiple doses in `addl` columns, expand with x$expand(); or etExpand(x)
#> -- First part of x: -----
#> # A tibble: 101 x 6
#>   time    amt    ii addl evid      dur
#>   [h] <dbl> [h] <int> <evid> [h]
#> 1 0.0000000 NA    NA    NA 0:Observation NA
#> 2 0.0000000 10000 12    2 1:Dose (Add) 8
#> 3 0.2424242 NA    NA    NA 0:Observation NA
#> 4 0.4848485 NA    NA    NA 0:Observation NA
#> 5 0.7272727 NA    NA    NA 0:Observation NA
#> 6 0.9696970 NA    NA    NA 0:Observation NA
#> 7 1.2121212 NA    NA    NA 0:Observation NA
#> 8 1.4545455 NA    NA    NA 0:Observation NA
#> 9 1.6969697 NA    NA    NA 0:Observation NA
#> 10 1.9393939 NA    NA    NA 0:Observation NA
#> # ... with 91 more rows
```

```
rxSolve(m1, ev) %>% plot(depot, C2) +
  xlab("Time")
```

It can be also specified by the rate component:

```
ev <- et(timeUnits="hr") %>%
  et(amt=10000, ii=12, until=24, rate=10000/8) %>%
  et(seq(0, 24, length.out=100))

ev
```

```
#> ----- EventTable with 101 records -----
#>
#> 1 dosing records (see x$get.dosing(); add with add.dosing or et)
#> 100 observation times (see x$get.sampling(); add with add.sampling or et)
#> multiple doses in `addl` columns, expand with x$expand(); or etExpand(x)
#> -- First part of x: -----
#> # A tibble: 101 x 6
#>   time    amt rate      ii addl evid
#>   [h] <dbl> <rate/dur> [h] <int> <evid>
#> 1 0.0000000    NA NA      NA    NA 0:Observation
#> 2 0.0000000 10000 1250     12    2 1:Dose (Add)
#> 3 0.2424242    NA NA      NA    NA 0:Observation
#> 4 0.4848485    NA NA      NA    NA 0:Observation
#> 5 0.7272727    NA NA      NA    NA 0:Observation
#> 6 0.9696970    NA NA      NA    NA 0:Observation
#> 7 1.2121212    NA NA      NA    NA 0:Observation
#> 8 1.4545455    NA NA      NA    NA 0:Observation
#> 9 1.6969697    NA NA      NA    NA 0:Observation
#> 10 1.9393939    NA NA      NA    NA 0:Observation
#> # ... with 91 more rows
```

```
rxSolve(m1, ev) %>% plot(depot, C2) +
  xlab("Time")
```

These are the same with the exception of how bioavailability changes the infusion.

In the case of modeling rate, a bioavailability decrease, decreases the infusion duration, as in NONMEM. For example:

```
rxSolve(m1, ev, c(fdepot=0.25)) %>% plot(depot, C2) +  
  xlab("Time")
```

Similarly increasing the bioavailability increases the infusion duration.

```
rxSolve(m1, ev, c(fdepot=1.25)) %>% plot(depot, C2) +  
  xlab("Time")
```

The rationale for this behavior is that the rate and amt are specified by the event table, so the only thing that can change with a bioavailability increase is the duration of the infusion.

If you specify the amt and dur components in the event table, bioavailability changes affect the rate of infusion.

```
ev <- et(timeUnits="hr") %>%
  et(amt=10000, ii=12, until=24, dur=8) %>%
  et(seq(0, 24, length.out=100))
```

You can see the side-by-side comparison of bioavailability changes affecting rate instead of duration with these records in the following plots:

```
library(ggplot2)
library(patchwork)

p1 <- rxSolve(m1, ev, c(fdepot=1.25)) %>% plot(depot) +
  xlab("Time") + ylim(0,5000)

p2 <- rxSolve(m1, ev, c(fdepot=0.25)) %>% plot(depot) +
  xlab("Time")+ ylim(0,5000)

### Use patchwork syntax to combine plots
p1 * p2
```

7.3.2 Modeled Rate and Duration of Infusion

You can model the duration, which is equivalent to NONMEM's `rate=-2`. As a mnemonic you can use the `dur=model` instead of `rate=-2`

```
ev <- et(timeUnits="hr") %>%
  et(amt=10000, ii=12, until=24, dur=model) %>%
  et(seq(0, 24, length.out=100))

ev
```

```
#> ----- EventTable with 101 records -----
#>
#> 1 dosing records (see x$get.dosing(); add with add.dosing or et)
#> 100 observation times (see x$get.sampling(); add with add.sampling or et)
#> multiple doses in `addl` columns, expand with x$expand(); or etExpand(x)
#> -- First part of x: -----
#> # A tibble: 101 x 6
#>   time    amt rate      ii addl evid
#>   [h] <dbl> <rate/dur> [h] <int> <evid>
#> 1 0.0000000    NA NA      NA    NA 0:Observation
#> 2 0.0000000 10000 -2:dur    12     2 1:Dose (Add)
#> 3 0.2424242    NA NA      NA    NA 0:Observation
#> 4 0.4848485    NA NA      NA    NA 0:Observation
#> 5 0.7272727    NA NA      NA    NA 0:Observation
#> 6 0.9696970    NA NA      NA    NA 0:Observation
#> 7 1.2121212    NA NA      NA    NA 0:Observation
#> 8 1.4545455    NA NA      NA    NA 0:Observation
#> 9 1.6969697    NA NA      NA    NA 0:Observation
#> 10 1.9393939    NA NA      NA    NA 0:Observation
#> # ... with 91 more rows
```

```
rxSolve(m1, ev, c(durDepot=7)) %>% plot(depot, C2) +
  xlab("Time")
```

Similarly, you may also model rate. This is equivalent to NONMEM's `rate=-1` and is how RxODE's event table specifies the data item as well. You can also use `rate=model` as a mnemonic:

```
ev <- et(timeUnits="hr") %>%
  et(amt=10000, ii=12,until=24, rate=model) %>%
  et(seq(0, 24, length.out=100))
```

```
ev
```

```
#> ----- EventTable with 101 records -----
#>
#> 1 dosing records (see x$get.dosing(); add with add.dosing or et)
#> 100 observation times (see x$get.sampling(); add with add.sampling or et)
#> multiple doses in `addl` columns, expand with x$expand(); or etExpand(x)
#> -- First part of x: -----
#> # A tibble: 101 x 6
#>   time    amt rate      ii addl evid
#>   [h] <dbl> <rate/dur> [h] <int> <evid>
#> 1 0.0000000    NA NA      NA    NA 0:Observation
#> 2 0.0000000 10000 -1:rate    12     2 1:Dose (Add)
#> 3 0.2424242    NA NA      NA    NA 0:Observation
#> 4 0.4848485    NA NA      NA    NA 0:Observation
#> 5 0.7272727    NA NA      NA    NA 0:Observation
#> 6 0.9696970    NA NA      NA    NA 0:Observation
```

```
#> 7 1.2121212 NA NA NA NA 0:Observation
#> 8 1.4545455 NA NA NA NA 0:Observation
#> 9 1.6969697 NA NA NA NA 0:Observation
#> 10 1.9393939 NA NA NA NA 0:Observation
#> # ... with 91 more rows
```

```
rxSolve(m1, ev, c(rateDepot=10000/3)) %>% plot(depot, C2) +
  xlab("Time")
```

7.4 Steady State

These doses are solved until a steady state is reached with a constant inter-dose interval.

```
ev <- et(timeUnits="hr") %>%
  et(amt=10000, ii=12, ss=1) %>%
  et(seq(0, 24, length.out=100))
```

```
ev
```

```
#> ----- EventTable with 101 records -----
#>
```

```

#> 1 dosing records (see x$get.dosing(); add with add.dosing or et)
#> 100 observation times (see x$get.sampling(); add with add.sampling or et)
#> -- First part of x: -----
#> # A tibble: 101 x 5
#>   time    amt    ii evid      ss
#>   [h] <dbl> [h] <evid> <int>
#> 1 0.0000000 NA    NA 0:Observation NA
#> 2 0.0000000 10000 12 1:Dose (Add) 1
#> 3 0.2424242 NA    NA 0:Observation NA
#> 4 0.4848485 NA    NA 0:Observation NA
#> 5 0.7272727 NA    NA 0:Observation NA
#> 6 0.9696970 NA    NA 0:Observation NA
#> 7 1.2121212 NA    NA 0:Observation NA
#> 8 1.4545455 NA    NA 0:Observation NA
#> 9 1.6969697 NA    NA 0:Observation NA
#> 10 1.9393939 NA    NA 0:Observation NA
#> # ... with 91 more rows

```

```
rxSolve(m1, ev) %>% plot(C2)
```

7.4.1 Steady state for complex dosing

By using the `ss=2` flag, you can use the super-positioning principle in linear kinetics to get steady state nonstandard dosing (i.e. morning 100 mg vs evening 150 mg).

This is done by:

- Saving all the state values
- Resetting all the states and solving the system to steady state
- Adding back all the prior state values

```
ev <- et(timeUnits="hr") %>%
  et(amt=10000, ii=24, ss=1) %>%
  et(time=12, amt=15000, ii=24, ss=2) %>%
  et(time=24, amt=10000, ii=24, addl=3) %>%
  et(time=36, amt=15000, ii=24, addl=3) %>%
  et(seq(0, 64, length.out=500))

library(ggplot2)

rxSolve(m1, ev, maxsteps=10000) %>% plot(C2) +
  annotate("rect", xmin=0, xmax=24, ymin=-Inf, ymax=Inf,
    alpha=0.2) +
  annotate("text", x=12.5, y=7,
    label="Initial Steady State Period") +
  annotate("text", x=44, y=7,
    label="Steady State AM/PM dosing")
```

You can see that it takes a full dose cycle to reach the true complex steady state dosing.

7.4.2 Steady state for constant infusion or zero order processes

The last type of steady state that RxODE supports is steady-state constant infusion rate. This can be specified the same way as NONMEM, that is:

- No inter-dose interval `ii=0`
- A steady state dose, ie `ss=1`
- Either a positive rate (`rate>0`) or a estimated rate `rate=-1`.
- A zero dose, ie `amt=0`
- Once the steady-state constant infusion is achieved, the infusion is turned off when using this record, just like NONMEM.

Note that `rate=-2` where we model the duration of infusion doesn't make much sense since we are solving the infusion until steady state. The duration is specified by the steady state solution.

Also note that bioavailability changes on this steady state infusion also do not make sense because they neither change the rate or the duration of the steady state infusion. Hence modeled bioavailability on this type of dosing event is ignored.

Here is an example:

```
ev <- et(timeUnits="hr") %>%
  et(amt=0, ss=1, rate=10000/8)

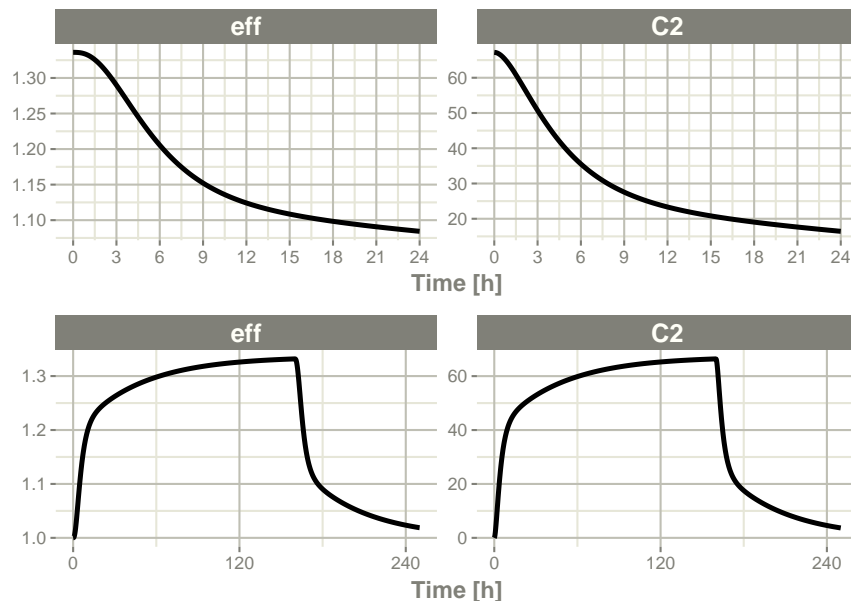

p1 <- rxSolve(m1, ev) %>% plot(C2, eff)

ev <- et(timeUnits="hr") %>%
  et(amt=200000, rate=10000/8) %>%
  et(0, 250, length.out=1000)

p2 <- rxSolve(m1, ev) %>% plot(C2, eff)

library(patchwork)

p1 / p2
```

Not only can this be used for PK, it can be used for steady-state disease processes.

7.5 Reset Events

Reset events are implemented by `evid=3` or `evid=reset`, for reset and `evid=4` for reset and dose.

```
ev <- et(timeUnits="hr") %>%
  et(amt=10000, ii=12, addl=3) %>%
  et(time=6, evid=reset) %>%
  et(seq(0, 24, length.out=100))
```

ev

```
#> ----- EventTable with 102 records -----
#>
#> 2 dosing records (see x$get.dosing(); add with add.dosing or et)
#> 100 observation times (see x$get.sampling(); add with add.sampling or et)
#> multiple doses in `addl` columns, expand with x$expand(); or etExpand(x)
#> -- First part of x: -----
#> # A tibble: 102 x 5
#>   time    amt    ii  addl evid
#>   [h] <dbl> [h] <int> <evid>
```

```
#> 1 0.0000000 NA NA NA 0:Observation
#> 2 0.0000000 10000 12 3 1:Dose (Add)
#> 3 0.2424242 NA NA NA 0:Observation
#> 4 0.4848485 NA NA NA 0:Observation
#> 5 0.7272727 NA NA NA 0:Observation
#> 6 0.9696970 NA NA NA 0:Observation
#> 7 1.2121212 NA NA NA 0:Observation
#> 8 1.4545455 NA NA NA 0:Observation
#> 9 1.6969697 NA NA NA 0:Observation
#> 10 1.9393939 NA NA NA 0:Observation
#> # ... with 92 more rows
```

The solving show what happens in this system when the system is reset at 6 hours post-dose.

```
rxSolve(m1, ev) %>% plot(depot, C2, eff)
```

You can see all the compartments are reset to their initial values. The next dose start the dosing cycle over.

```
ev <- et(timeUnits="hr") %>%
  et(amt=10000, ii=12, addl=3) %>%
  et(time=6, amt=10000, evid=4) %>%
  et(seq(0, 24, length.out=100))
```

```
ev
```

```
#> ----- EventTable with 102 records -----
#>
#> 2 dosing records (see x$get.dosing(); add with add.dosing or et)
#> 100 observation times (see x$get.sampling(); add with add.sampling or et)
#> multiple doses in `addl` columns, expand with x$expand(); or etExpand(x)
#> -- First part of x: -----
#> # A tibble: 102 x 5
#>   time    amt    ii addl evid
#>   [h] <dbl> [h] <int> <evid>
#> 1 0.0000000    NA    NA    NA 0:Observation
#> 2 0.0000000 10000    12     3 1:Dose (Add)
#> 3 0.2424242    NA    NA    NA 0:Observation
#> 4 0.4848485    NA    NA    NA 0:Observation
#> 5 0.7272727    NA    NA    NA 0:Observation
#> 6 0.9696970    NA    NA    NA 0:Observation
#> 7 1.2121212    NA    NA    NA 0:Observation
#> 8 1.4545455    NA    NA    NA 0:Observation
#> 9 1.6969697    NA    NA    NA 0:Observation
#> 10 1.9393939    NA    NA    NA 0:Observation
#> # ... with 92 more rows
```

In this case, the whole system is reset and the dose is given

```
rxSolve(m1, ev) %>% plot(depot, C2, eff)
```

7.6 Turning off compartments

You may also turn off a compartment, which is similar to a reset event.

```
ev <- et(timeUnits="hr") %>%
  et(amt=10000, ii=12, addl=3) %>%
  et(time=6, cmt="-depot", evid=2) %>%
  et(seq(0, 24, length.out=100))
```

ev

```
#> ----- EventTable with 102 records -----
#>
#> 2 dosing records (see x$get.dosing(); add with add.dosing or et)
#> 100 observation times (see x$get.sampling(); add with add.sampling or et)
#> multiple doses in `addl` columns, expand with x$expand(); or etExpand(x)
#> -- First part of x: -----
#> # A tibble: 102 x 6
#>       time cmt      amt    ii addl evid
#>   [h] <chr>   <dbl> [h] <int> <evid>
#> 1 0.0000000 (obs)    NA   NA    NA 0:Observation
#> 2 0.0000000 (default) 10000  12    3 1:Dose (Add)
```

```
#> 3 0.2424242 (obs)      NA    NA    NA 0:Observation
#> 4 0.4848485 (obs)      NA    NA    NA 0:Observation
#> 5 0.7272727 (obs)      NA    NA    NA 0:Observation
#> 6 0.9696970 (obs)      NA    NA    NA 0:Observation
#> 7 1.2121212 (obs)      NA    NA    NA 0:Observation
#> 8 1.4545455 (obs)      NA    NA    NA 0:Observation
#> 9 1.6969697 (obs)      NA    NA    NA 0:Observation
#> 10 1.9393939 (obs)     NA    NA    NA 0:Observation
#> # ... with 92 more rows
```

Solving shows what this does in the system:

```
rxSolve(m1, ev) %>% plot(depot, C2, eff)
```

In this case, the depot is turned off, and the depot compartment concentrations are set to the initial values but the other compartment concentrations/levels are not reset. When another dose to the depot is administered the depot compartment is turned back on.

Note that a dose to a compartment only turns back on the compartment that was dosed. Hence if you turn off the effect compartment, it continues to be off after another dose to the depot.

```

ev <- et(timeUnits="hr") %>%
  et(amt=10000, ii=12, addl=3) %>%
  et(time=6, cmt="-eff", evid=2) %>%
  et(seq(0, 24, length.out=100))

rxSolve(m1, ev) %>% plot(depot,C2, eff)

```

To turn back on the compartment, a zero-dose to the compartment or a `evid=2` with the compartment would be needed.

```

ev <- et(timeUnits="hr") %>%
  et(amt=10000, ii=12, addl=3) %>%
  et(time=6, cmt="-eff", evid=2) %>%
  et(time=12, cmt="eff", evid=2) %>%
  et(seq(0, 24, length.out=100))

rxSolve(m1, ev) %>% plot(depot,C2, eff)

```

7.7 Classic RxODE events

Originally RxODE supported compound event IDs; RxODE still supports these parameters, but it is often more useful to use the the normal NONMEM dataset standard that is used by many modeling tools like NONMEM, Monolix and nlmixr, described in the [RxODE event types](#) article.

Classically, RxODE supported event coding in a single event id `evid` described in the following table.

100+ cmt	Infusion/Event Flag	<99 Cmt	SS flag & Turning of Compartment
100+ cmt	0 = bolus dose	< 99 cmt	1 = dose
	1 = infusion (rate)		10 = Steady state 1 (equivalent to SS=1)
	2 = infusion (dur)		20 = Steady state 2 (equivalent to SS=2)
	6 = turn off modeled duration		30 = Turn off a compartment (equivalent to -CMT w/EVID=2)
	7 = turn off modeled rate		
	8 = turn on modeled duration		

100+ cmt	Infusion/Event Flag	<99 Cmt	SS flag & Turning of Compartment
	9 = turn on modeled rate		
	4 = replace event		
	5 = multiply event		

The classic EVID concatenate the numbers in the above table, so an infusion would to compartment 1 would be 10101 and an infusion to compartment 199 would be 119901.

EVID = 0 (observations), EVID=2 (other type event) and EVID=3 are all supported. Internally an EVID=9 is a non-observation event and makes sure the system is initialized to zero; EVID=9 should not be manually set. EVID 10-99 represents modeled time interventions, similar to NONMEM's MTIME. This along with amount (amt) and time columns specify the events in the ODE system.

For infusions specified with EVIDs > 100 the amt column represents the rate value.

For Infusion flags 1 and 2 +amt turn on the infusion to a specific compartment -amt turn off the infusion to a specific compartment. To specify a dose/duration you place the dosing records at the time the duration starts or stops.

For modeled rate/duration infusion flags the on infusion flag must be followed by an off infusion record.

These number are concatenated together to form a full RxODE event ID, as shown in the following examples:

7.7.1 Bolus Dose Examples

A 100 bolus dose to compartment #1 at time 0

time	evid	amt
0	101	100
0.5	0	0
1	0	0

A 100 bolus dose to compartment #99 at time 0

time	evid	amt
0	9901	100
0.5	0	0
1	0	0

A 100 bolus dose to compartment #199 at time 0

time	evid	amt
0	109901	100
0.5	0	0
1	0	0

7.7.2 Infusion Event Examples

Bolus infusion with rate 50 to compartment 1 for 1.5 hr, (modeled bioavailability changes duration of infusion)

time	evid	amt
0	10101	50
0.5	0	0
1	0	0
1.5	10101	-50

Bolus infusion with rate 50 to compartment 1 for 1.5 hr (modeled bioavailability changes rate of infusion)

time	evid	amt
0	20101	50
0.5	0	0
1	0	0
1.5	20101	-50

Modeled rate with amount of 50

time	evid	amt
0	90101	50
0	70101	50
0.5	0	0
1	0	0

Modeled duration with amount of 50

time	evid	amt
0	80101	50
0	60101	50
0.5	0	0
1	0	0

7.7.3 Steady State for classic RxODE EVID example

Steady state dose to cmt 1

time	evid	amt
0	110	50

Steady State with super-positioning principle for am 50 and pm 100 dose

time	evid	amt
0	110	50
12	120	100

7.7.4 Turning off a compartment with classic RxODE EVID

Turn off the first compartment at time 12

time	evid	amt
0	110	50
12	130	NA

Event coding in RxODE is encoded in a single event number evid. For compartments under 100, this is coded as:

- This event is 0 for observation events.
- For a specified compartment a bolus dose is defined as:
 - $100 * (\text{Compartment Number}) + 1$
 - The dose is then captured in the amt
- For IV bolus doses the event is defined as:
 - $10000 + 100 * (\text{Compartment Number}) + 1$
 - The infusion rate is captured in the amt column

- The infusion is turned off by subtracting amt with the same evid at the stop of the infusion.

For compartments greater or equal to 100, the 100s place and above digits are transferred to the 100,000th place digit. For doses to the 99th compartment the evid for a bolus dose would be 9901 and the evid for an infusion would be 19901. For a bolus dose to the 199th compartment the evid for the bolus dose would be 109901. An infusion dosing record for the 199th compartment would be 119901.

Chapter 8

Easily creating RxODE events

An event table in RxODE is a specialized data frame that acts as a container for all of RxODE's events and observation times.

To create an RxODE event table you may use the code `eventTable()`, `et()`, or even create your own data frame with the right event information contained in it. This is closely related to the [types of events that RxODE supports](#).

```
library(RxODE)
(ev <- eventTable())
```

```
#> ----- EventTable with 0 records -----
#>
#>    0 dosing records (see x$get.dosing(); add with add.dosing or et)
#>    0 observation times (see x$get.sampling(); add with add.sampling or et)
```

or

```
(ev <- et())
```

```
#> ----- EventTable with 0 records -----
#>
#>    0 dosing records (see x$get.dosing(); add with add.dosing or et)
#>    0 observation times (see x$get.sampling(); add with add.sampling or et)
```

With this event table you can add sampling/observations or doses by piping or direct access.

This is a short table of the two main functions to create dosing

add.dosing()	et()	Description
dose	amt	Dose/Rate/Duration amount
nbr.doses	addl	Additional doses or number of doses
dosing.interval	ii	Dosing Interval
dosing.to	cmt	Dosing Compartment
rate	rate	Infusion rate
start.time	time	Dosing start time
	dur	Infusion Duration

Sampling times can be added with `add.sampling(sampling times)` or `et(sampling times)`. **Dosing intervals and sampling windows** are also supported.

For these models, we can illustrate by using the model shared in the RxODE tutorial:

```
## Model from RxODE tutorial
m1 <-RxODE({
  KA=2.94E-01;
  CL=1.86E+01;
  V2=4.02E+01;
  Q=1.05E+01;
  V3=2.97E+02;
  Kin=1;
  Kout=1;
  EC50=200;
  ## Added modeled bioavaiblity, duration and rate
  fdepot = 1;
  durDepot = 8;
  rateDepot = 1250;
  C2 = centr/V2;
  C3 = peri/V3;
  d/dt(depot) =-KA*depot;
  f(depot) = fdepot
  dur(depot) = durDepot
  rate(depot) = rateDepot
  d/dt(centr) = KA*depot - CL*C2 - Q*C2 + Q*C3;
  d/dt(peri) = Q*C2 - Q*C3;
  d/dt(eff) = Kin - Kout*(1-C2/(EC50+C2))*eff;
  eff(0) = 1
})
```

8.1 Adding doses to the event table

Once created you can add dosing to the event table by the `add.dosing()`, and `et()` functions.

Using the `add.dosing()` function you have:

argument	meaning
dose	dose amount
nbr.doses	Number of doses; Should be at least 1.
dosing.interval	Dosing interval; By default this is 24.
dosing.to	Compartment where dose is administered.
rate	Infusion rate
start.time	The start time of the dose

```
ev <- eventTable(amount.units="mg", time.units="hr")

## The methods are attached to the event table, so you can use
## them directly
ev$add.dosing(dose=10000, nbr.doses = 3)# loading doses
## Starts at time 0; Default dosing interval is 24

## You can also pipe the event tables to these methods.
ev <- ev %>%
  add.dosing(dose=5000, nbr.doses=14,
             dosing.interval=12)# maintenance

ev

#> ----- EventTable with 2 records -----
#>
#> 2 dosing records (see x$get.dosing(); add with add.dosing or et)
#> 0 observation times (see x$get.sampling(); add with add.sampling or et)
#> multiple doses in `addl` columns, expand with x$expand(); or etExpand(x)
#> -- First part of x: -----
#> # A tibble: 2 x 5
#>   time   amt   ii addl evid
#>   [h] [mg] [h] <int> <evid>
#> 1     0 10000   24     2 1:Dose (Add)
#> 2     0  5000   12    13 1:Dose (Add)
```

Notice that the units were specified in the table. When specified, the units use the `units` package to keep track of the units and convert them if needed. Additionally,

ggforce uses them to label the ggplot axes. The `set_units` and `drop_units` are useful to set and drop the RxODE event table units.

In this example, you can see the time axes is labeled:

```
rxSolve(m1, ev) %>% plot(C2)
```

If you are more familiar with the NONMEM/RxODE event records, you can also specify dosing using `et` with the dose elements directly:

```
ev <- et(timeUnits="hr") %>%
  et(amt=10000, until = set_units(3, days),
     ii=12) # loading doses
```

```
ev
```

```
#> ----- EventTable with 1 records -----
#>
#> 1 dosing records (see x$get.dosing(); add with add.dosing or et)
#> 0 observation times (see x$get.sampling(); add with add.sampling or et)
#> multiple doses in `addl` columns, expand with x$expand(); or etExpand(x)
#> -- First part of x: -----
#> # A tibble: 1 x 5
#>   time    amt    ii  addl evid
#>   [h] <dbl> [h] <int> <evid>
#> 1     0 10000    12     6 1:Dose (Add)
```

Which gives:

```
rxSolve(m1, ev) %>% plot(C2)
```

This shows how easy creating event tables can be.

8.2 Adding sampling to an event table

If you notice in the above examples, RxODE generated some default sampling times since there was not any sampling times. If you wish more control over the sampling time, you should add the samples to the RxODE event table by `add.sampling` or `et`

```
ev <- eventTable(amount.units="mg", time.units="hr")  
  
## The methods are attached to the event table, so you can use them  
## directly  
ev$add.dosing(dose=10000, nbr.doses = 3) # loading doses  
  
ev$add.sampling(seq(0, 24, by=4))  
  
ev
```

```
#> ----- EventTable with 8 records -----
#>
#> 1 dosing records (see x$get.dosing(); add with add.dosing or et)
#> 7 observation times (see x$get.sampling(); add with add.sampling or et)
#> multiple doses in `addl` columns, expand with x$expand(); or etExpand(x)
#> -- First part of x: -----
#> # A tibble: 8 x 5
#>   time    amt    ii addl evid
#>   [h]  [mg]  [h] <int> <evid>
#> 1     0    NA    NA    NA 0:Observation
#> 2     0 10000    24     2 1:Dose (Add)
#> 3     4    NA    NA    NA 0:Observation
#> 4     8    NA    NA    NA 0:Observation
#> 5    12    NA    NA    NA 0:Observation
#> 6    16    NA    NA    NA 0:Observation
#> 7    20    NA    NA    NA 0:Observation
#> 8    24    NA    NA    NA 0:Observation
```

Which gives:

```
solve(m1, ev) %>% plot(C2)
```

Or if you use `et` you can simply add them in a similar way to `add.sampling`:

```
ev <- et(timeUnits="hr") %>%
  et(amt=10000, until = set_units(3, days),
     ii=12) %>% # loading doses
  et(seq(0,24,by=4))

ev
```

```
#> ----- EventTable with 8 records -----
#>
#> 1 dosing records (see x$get.dosing(); add with add.dosing or et)
#> 7 observation times (see x$get.sampling(); add with add.sampling or et)
#> multiple doses in `addl` columns, expand with x$expand(); or etExpand(x)
#> -- First part of x: -----
#> # A tibble: 8 x 5
#>   time    amt    ii addl evid
#>   [h] <dbl> [h] <int> <evid>
#> 1     0     NA    NA    NA 0:Observation
#> 2     0 10000    12     6 1:Dose (Add)
#> 3     4     NA    NA    NA 0:Observation
#> 4     8     NA    NA    NA 0:Observation
#> 5    12     NA    NA    NA 0:Observation
#> 6    16     NA    NA    NA 0:Observation
#> 7    20     NA    NA    NA 0:Observation
#> 8    24     NA    NA    NA 0:Observation
```

which gives the following RxODE solve:

```
solve(m1, ev) %>% plot(C2)
```

Note the jagged nature of these plots since there was only a few sample times.

8.3 Expand the event table to a multi-subject event table.

The only thing that is needed to expand an event table is a list of IDs that you want to expand;

```
ev <- et(timeUnits="hr") %>%
  et(amt=10000, until = set_units(3, days),
    ii=12) %>% # loading doses
  et(seq(0,48,length.out=200)) %>%
  et(id=1:4)
```

ev

```
#> ----- EventTable with 804 records -----
#> 4 individuals
#> 4 dosing records (see x$get.dosing(); add with add.dosing or et)
#> 800 observation times (see x$get.sampling(); add with add.sampling or et)
#> multiple doses in `addl` columns, expand with x$expand(); or etExpand(x)
#> -- First part of x: -----
```

```
#> # A tibble: 804 x 6
#>       id      time  amt    ii  addl evid
#>   <int>    [h] <dbl>  [h] <int> <evid>
#> 1     1  0.0000000    NA    NA    NA 0:Observation
#> 2     1  0.0000000 10000    12     6 1:Dose (Add)
#> 3     1  0.2412060    NA    NA    NA 0:Observation
#> 4     1  0.4824121    NA    NA    NA 0:Observation
#> 5     1  0.7236181    NA    NA    NA 0:Observation
#> 6     1  0.9648241    NA    NA    NA 0:Observation
#> 7     1  1.2060302    NA    NA    NA 0:Observation
#> 8     1  1.4472362    NA    NA    NA 0:Observation
#> 9     1  1.6884422    NA    NA    NA 0:Observation
#> 10    1  1.9296482    NA    NA    NA 0:Observation
#> # ... with 794 more rows
```

You can see in the following simulation there are 4 individuals that are solved for:

```
set.seed(42)
solve(m1, ev,
      params=data.frame(KA=0.294*exp(rnorm(4)),
                        18.6*exp(rnorm(4)))) %>%
  plot(C2)
```

```
#> Warning: 'ID' missing in 'parameters' dataset
#> individual parameters are assumed to have the same order as the event dataset
```

8.4 Add doses and samples within a sampling window

In addition to adding fixed doses and fixed sampling times, you can have windows where you sample and draw doses from. For dosing windows you specify the time as an ordered numerical vector with the lowest dosing time and the highest dosing time inside a list.

In this example, you start with a dosing time with a 6 hour dosing window:

```
set.seed(42)
ev <- et(timeUnits="hr") %>%
  et(time=list(c(0,6)), amt=10000, until = set_units(2, days),
      ii=12) %>% # loading doses
  et(id=1:4)

ev
```

```
#> ----- EventTable with 16 records -----
#>      4 individuals
#>      16 dosing records (see x$get.dosing(); add with add.dosing or et)
#>      0 observation times (see x$get.sampling(); add with add.sampling or et)
#> -- First part of x: -----
#> # A tibble: 16 x 6
#>       id    low      time    high    amt evid
#>   <int>  [h]      [h]    [h] <dbl> <evid>
#> 1     1     0  5.4888363     6 10000 1:Dose (Add)
#> 2     1    12 16.9826858    18 10000 1:Dose (Add)
#> 3     1    24 25.7168372    30 10000 1:Dose (Add)
#> 4     1    36 41.6224525    42 10000 1:Dose (Add)
#> 5     2     0  4.3146735     6 10000 1:Dose (Add)
#> 6     2    12 14.7464507    18 10000 1:Dose (Add)
#> 7     2    24 28.2303887    30 10000 1:Dose (Add)
#> 8     2    36 39.9419537    42 10000 1:Dose (Add)
#> 9     3     0  0.8079996     6 10000 1:Dose (Add)
#> 10    3    12 16.4195299    18 10000 1:Dose (Add)
#> 11    3    24 27.1145757    30 10000 1:Dose (Add)
#> 12    3    36 39.8504731    42 10000 1:Dose (Add)
#> 13    4     0  4.9826858     6 10000 1:Dose (Add)
#> 14    4    12 13.7168372    18 10000 1:Dose (Add)
#> 15    4    24 29.6224525    30 10000 1:Dose (Add)
#> 16    4    36 41.4888363    42 10000 1:Dose (Add)
```

You can clearly see different dosing times in the following simulation:

```
ev <- ev %>% et(seq(0,48,length.out=200))  
  
solve(m1, ev,  
      params=data.frame(KA=0.294*exp(rnorm(4)),  
                        18.6*exp(rnorm(4)))) %>%  
plot(C2)
```

```
#> Warning: 'ID' missing in 'parameters' dataset
#> individual parameters are assumed to have the same order as the event dataset
```

Of course in reality the dosing interval may only be 2 hours:

[illegible]

```
#> Warning: 'ID' missing in 'parameters' dataset
#> individual parameters are assumed to have the same order as the event dataset
```

The same sort of thing can be specified with sampling times. To specify the sampling times in terms of a sampling window, you can create a list of the sampling times. Each sampling time will be a two element ordered numeric vector.

```
set.seed(42)
ev <- et(timeUnits="hr") %>%
  et(time=list(c(0,2)), amt=10000, until = set_units(2, days),
      ii=12) %>% # loading doses
  et(id=1:4)

## Create 20 samples in the first 24 hours and 20 samples in the
## second 24 hours
samples <- c(lapply(1:20, function(...){c(0,24)}),
             lapply(1:20, function(...){c(20,48)}))

## Add the random collection to the event table
ev <- ev %>% et(samples)

library(ggplot2)
solve(m1, ev, params=data.frame(KA=0.294*exp(rnorm(4)),
                                18.6*exp(rnorm(4)))) %>%
  plot(C2) + geom_point()
```

```
#> Warning: 'ID' missing in 'parameters' dataset
#> individual parameters are assumed to have the same order as the event dataset
```

This shows the flexibility in dosing and sampling that the RxODE event tables allow.

8.5 Combining event tables

Since you can create dosing records and sampling records, you can create any complex dosing regimen you wish. In addition, RxODE allows you to combine event tables by `c`, `seq`, `rep`, and `rbind`.

8.6 Sequencing event tables

One way to combine event table is to sequence them by `c`, `seq` or `etSeq`. This takes the two dosing groups and adds at least one inter-dose interval between them:

```
## bid for 5 days
bid <- et(timeUnits="hr") %>%
  et(amt=10000,ii=12,until=set_units(5, "days"))

## qd for 5 days
```

```

qd <- et(timeUnits="hr") %>%
  et(amt=20000,ii=24,until=set_units(5, "days"))

## bid for 5 days followed by qd for 5 days
et <- seq(bid,qd) %>% et(seq(0,11*24,length.out=100));

rxSolve(m1, et) %>% plot(C2)

```

When sequencing events, you can also separate this sequence by a period of time; For example if you wanted to separate this by a week, you could easily do that with the following sequence of event tables:

```

## bid for 5 days followed by qd for 5 days
et <- seq(bid,set_units(1, "week"), qd) %>%
  et(seq(0,18*24,length.out=100));

rxSolve(m1, et) %>% plot(C2)

```

Note that in this example the time between the bid and the qd event tables is exactly one week, not 1 week plus 24 hours because of the inter-dose interval. If you want that behavior, you can sequence it using the `wait="+ii"`.

```
## bid for 5 days followed by qd for 5 days
et <- seq(bid, set_units(1, "week"), qd, wait="+ii") %>%
  et(seq(0, 18*24, length.out=100));

rxSolve(m1, et) %>% plot(C2)
```

Also note, that RxODE assumes that the dosing is what you want to space the event tables by, and clears out any sampling records when you combine the event tables. If that is not true, you can also use the option `samples="use"`

8.7 Repeating event tables

You can have an event table that you can repeat with `etRep` or `rep`. For example 4 rounds of 2 weeks on QD therapy and 1 week off of therapy can be simply specified:

```
qd <- et(timeUnits = "hr") %>%
  et(amt=10000, ii=24, until=set_units(2, "weeks"), cmt="depot")

et <- rep(qd, times=4, wait=set_units(1, "weeks")) %>%
  add.sampling(set_units(seq(0, 12.5, by=0.005), weeks))

rxSolve(m1, et) %>% plot(C2)
```

This is a simplified way to use a sequence of event tables. Therefore, many of the same options still apply; That is samples are cleared unless you use `samples="use"`, and the time between event tables is at least the inter-dose interval. You can adjust the timing by the `wait` option.

8.8 Combining event tables with rbind

You may combine event tables with `rbind`. This does not consider the event times when combining the event tables, but keeps them the same times. If you space the event tables by a waiting period, it also does not consider the inter-dose interval.

Using the previous `seq` you can clearly see the difference. Here was the sequence:

```
## bid for 5 days
bid <- et(timeUnits="hr") %>%
  et(amt=10000,ii=12,until=set_units(5, "days"))

## qd for 5 days
qd <- et(timeUnits="hr") %>%
  et(amt=20000,ii=24,until=set_units(5, "days"))

et <- seq(bid,qd) %>%
  et(seq(0,18*24,length.out=500));
```

```
rxSolve(m1, et) %>% plot(C2)
```

But if you bind them together with `rbind`

```
## bid for 5 days  
et <- rbind(bid,qd) %>%  
  et(seq(0,18*24,length.out=500));  
  
rxSolve(m1, et) %>% plot(C2)
```

Still the waiting period applies (but does not consider the inter-dose interval)

```
et <- rbind(bid,wait=set_units(10,days),qd) %>%  
  et(seq(0,18*24,length.out=500));  
  
rxSolve(m1, et) %>% plot(C2)
```

You can also bind the tables together and make each ID in the event table unique; This can be good to combine cohorts with different expected dosing and sampling times. This requires the `id="unique"` option; Using the first example shows how this is different in this case:

```
## bid for 5 days
et <- etRbind(bid,qd, id="unique") %>%
  et(seq(0,150,length.out=500));

library(ggplot2)
rxSolve(m1, et) %>% plot(C2) + facet_wrap( ~ id)
```

8.9 Expanding events

Event tables can be expanded so they contain an `addl` data item, like the following example:

```
ev <- et() %>%
  et(dose=50, ii=8, until=48)

ev

#> ----- EventTable with 1 records -----
#>
#> 1 dosing records (see x$get.dosing(); add with add.dosing or et)
#> 0 observation times (see x$get.sampling(); add with add.sampling or et)
#> multiple doses in `addl` columns, expand with x$expand(); or etExpand(x)
#> -- First part of x: -----
#> # A tibble: 1 x 5
#>   time  amt  ii  addl evid
#>   <dbl> <dbl> <dbl> <int> <evid>
#> 1     0   50    8     6 1:Dose (Add)
```

You can expand the events so they do not have the `addl` items by `$expand()` or `etExpand(ev)`:

The first, `etExpand(ev)` expands the event table without modifying the original data frame:

```
etExpand(ev)
```

```
#> ----- EventTable with 7 records -----
#>
#> 7 dosing records (see x$get.dosing(); add with add.dosing or et)
#> 0 observation times (see x$get.sampling(); add with add.sampling or et)
#> -- First part of x: -----
#> # A tibble: 7 x 4
#>   time  amt   ii evid
#>   <dbl> <dbl> <dbl> <evid>
#> 1     0    50     0 1:Dose (Add)
#> 2     8    50     0 1:Dose (Add)
#> 3    16    50     0 1:Dose (Add)
#> 4    24    50     0 1:Dose (Add)
#> 5    32    50     0 1:Dose (Add)
#> 6    40    50     0 1:Dose (Add)
#> 7    48    50     0 1:Dose (Add)
```

You can see the `addl` events were expanded, however the original data frame remained intact:

```
print(ev)
```

```
#> ----- EventTable with 1 records -----
#>
#> 1 dosing records (see $get.dosing(); add with add.dosing or et)
#> 0 observation times (see $get.sampling(); add with add.sampling or et)
#> multiple doses in `addl` columns, expand with $expand(); or etExpand()
#> -- First part of : -----
#> # A tibble: 1 x 5
#>   time  amt   ii addl evid
#>   <dbl> <dbl> <dbl> <int> <evid>
#> 1     0    50     8     6 1:Dose (Add)
```

If you use `ev$expand()` it will modify the `ev` object. This is similar to an object-oriented method:

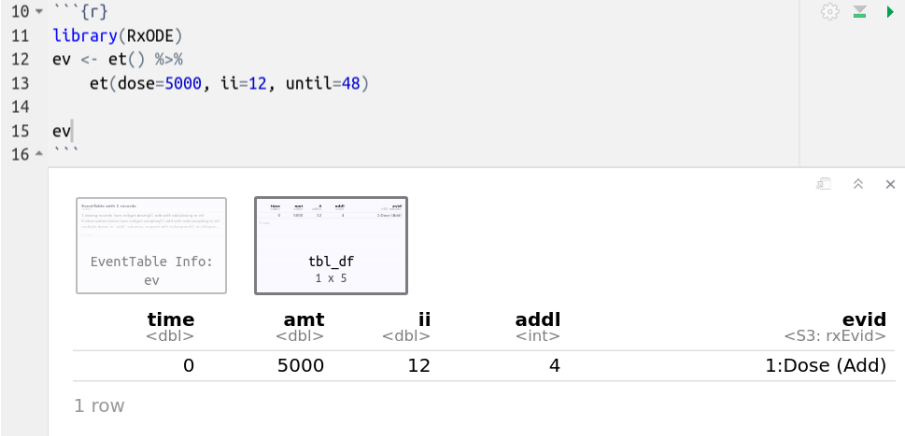

```
ev$expand()
ev
```

```
#> ----- EventTable with 7 records -----
#>
#> 7 dosing records (see x$get.dosing(); add with add.dosing or et)
#> 0 observation times (see x$get.sampling(); add with add.sampling or et)
#> -- First part of x: -----
#> # A tibble: 7 x 4
#>   time    amt    ii evid
#>   <dbl> <dbl> <dbl> <evid>
#> 1     0    50     0 1:Dose (Add)
#> 2     8    50     0 1:Dose (Add)
#> 3    16    50     0 1:Dose (Add)
#> 4    24    50     0 1:Dose (Add)
#> 5    32    50     0 1:Dose (Add)
#> 6    40    50     0 1:Dose (Add)
#> 7    48    50     0 1:Dose (Add)
```

8.10 Event tables in Rstudio Notebooks

In addition to the output in the console which has been shown in the above examples, Rstudio notebook output is different and can be seen in the following screenshots;

The first screenshot shows how the event table looks after evaluating it in the Rstudio notebook

The screenshot shows the RStudio notebook interface. The code editor contains the following R code:

```
10 {r}
11 library(RxODE)
12 ev <- et() %>%
13   et(dose=5000, ii=12, until=48)
14
15 ev
16
```

The output of the code is displayed in a viewer pane. It includes two small preview windows: "EventTable Info: ev" and "tbl_df 1 x 5". Below these, a table is shown with the following structure:

time <dbl>	amt <dbl>	ii <dbl>	addl <int>	evid <S3: rxEvid>
0	5000	12	4	1:Dose (Add)

Below the table, it indicates "1 row".

This is a simple dataframe that allows you to page through the contents. If you click on the first box in the Rstudio notebook output, it will have the notes about the event table:

```

10 {r}
11 library(RxODE)
12 ev <- et() %>%
13   et(dose=5000, ii=12, until=48)
14
15 ev
16

```

EventTable Info:

ev

tbl_df

1 x 5

EventTable with 1 records

<chr>

1 dosing records (see `ev$get.dosing()`; add with `add.dosing` or `et`)

0 observation times (see `ev$get.sampling()`; add with `add.sampling` or `et`)

multiple doses in ``addl`` columns, expand with `ev$expand()`; or `etExpand(ev)`

3 rows

Chapter 9

Solving and solving options

In general, ODEs are solved using a combination of:

- A compiled model specification from `RxODE()`, specified with `object=`
- Input parameters, specified with `params=` (and could be blank)
- Input data or event table, specified with `events=`
- Initial conditions, specified by `inits=` (and possibly in the model itself by `state(0)=`)

The solving options are given in the sections below:

9.1 General Solving Options

9.1.1 `object`

`object` is either a RxODE family of objects, or a file-name with a RxODE model specification, or a string with a RxODE model specification.

9.1.2 `params`

`params` a numeric named vector with values for every parameter in the ODE system; the names must correspond to the parameter identifiers used in the ODE specification;

9.1.3 events

`events` an `eventTable` object describing the input (e.g., doses) to the dynamic system and observation sampling time points (see `[eventTable()]`);

9.1.4 inits

`inits` a vector of initial values of the state variables (e.g., amounts in each compartment), and the order in this vector must be the same as the state variables (e.g., PK/PD compartments);

9.1.5 method

`method` The method for solving ODEs. Currently this supports:

- "liblsoda" thread safe lsoda. This supports parallel thread-based solving, and ignores user Jacobian specification.
- "lsoda" – LSODA solver. Does not support parallel thread-based solving, but allows user Jacobian specification.
- "dop853" – DOP853 solver. Does not support parallel thread-based solving nor user Jacobian specification
- "indLin" – Solving through inductive linearization. The RxODE dll must be setup specially to use this solving routine.

9.1.6 stiff

`stiff` a logical (TRUE by default) indicating whether the ODE system is stiff or not.

For stiff ODE systems (`stiff = TRUE`), RxODE uses the LSODA (Livermore Solver for Ordinary Differential Equations) Fortran package, which implements an automatic method switching for stiff and non-stiff problems along the integration interval, authored by Hindmarsh and Petzold (2003).

For non-stiff systems (`stiff = FALSE`), RxODE uses DOP853, an explicit Runge-Kutta method of order 8(5, 3) of Dormand and Prince as implemented in C by Hairer and Wanner (1993).

If `stiff` is not specified, the `method` argument is used instead.

9.2 lsoda/dop solving options

9.2.1 atol

atol a numeric absolute tolerance (1e-8 by default) used by the ODE solver to determine if a good solution has been achieved; This is also used in the solved linear model to check if prior doses do not add anything to the solution.

9.2.2 rtol

rtol a numeric relative tolerance (1e-6 by default) used by the ODE solver to determine if a good solution has been achieved. This is also used in the solved linear model to check if prior doses do not add anything to the solution.

9.2.3 maxsteps

maxsteps maximum number of (internally defined) steps allowed during one call to the solver. (5000 by default)

9.2.4 hmin

hmin The minimum absolute step size allowed. The default value is 0.

9.2.5 hmax

hmax The maximum absolute step size allowed. When **hmax**=NA (default), uses the average difference + **hmaxSd***sd in times and sampling events. The **hmaxSd** is a user specified parameter and which defaults to zero. When **hmax**=NULL R_xODE uses the maximum difference in times in your sampling and events. The value 0 is equivalent to infinite maximum absolute step size.

9.2.6 hmaxSd

hmaxSd The number of standard deviations of the time difference to add to **hmax**. The default is 0

9.2.7 hini

hini The step size to be attempted on the first step. The default value is determined by the solver (when **hini** = 0)

9.2.8 maxordn

maxordn The maximum order to be allowed for the nonstiff (Adams) method. The default is 12. It can be between 1 and 12.

9.2.9 maxords

maxords The maximum order to be allowed for the stiff (BDF) method. The default value is 5. This can be between 1 and 5.

9.2.10 mxhnil

mxhnil maximum number of messages printed (per problem) warning that $T + H = T$ on a step ($H = \text{step size}$). This must be positive to result in a non-default value. The default value is 0 (or infinite).

9.2.11 hmxl

hmxl inverse of the maximum absolute value of H to be used. $hmxl = 0.0$ is allowed and corresponds to an infinite $h_{\max 1}$ (default). h_{\min} and h_{\max} may be changed at any time, but will not take effect until the next change of H is considered. This option is only considered with `method="liblsoda"`.

9.2.12 istateReset

istateReset When TRUE, reset the ISTATE variable to 1 for lsoda and liblsoda with doses, like `deSolve`; When FALSE, do not reset the ISTATE variable with doses.

9.3 Inductive Linearization Options

9.3.1 indLinMatExpType

indLinMatExpType This is the matrix exponential type that is used for RxODE. Currently the following are supported:

- **Al-Mohy** Uses the exponential matrix method of Al-Mohy Higham (2009)
- **arma** Use the exponential matrix from RcppArmadillo
- **expokit** Use the exponential matrix from Roger B. Sidje (1998)

9.3.2 indLinMatExpOrder

`indLinMatExpOrder` an integer, the order of approximation to be used, for the `Al-Mohy` and `expokit` values. The best value for this depends on machine precision (and slightly on the matrix). We use 6 as a default.

9.3.3 indLinPhiTol

`indLinPhiTol` the requested accuracy tolerance on exponential matrix.

9.3.4 indLinPhiM

`indLinPhiM` the maximum size for the Krylov basis

9.4 Steady State Solving Options

9.4.1 minSS

`minSS` Minimum number of iterations for a steady-state dose

9.4.2 maxSS

`maxSS` Maximum number of iterations for a steady-state dose

9.4.3 strictSS

`strictSS` Boolean indicating if a strict steady-state is required. If a strict steady-state is (TRUE) required then at least `minSS` doses are administered and the total number of steady states doses will continue until `maxSS` is reached, or `atol` and `rtol` for every compartment have been reached. However, if ODE solving problems occur after the `minSS` has been reached the whole subject is considered an invalid solve. If `strictSS` is FALSE then as long as `minSS` has been reached the last good solve before ODE solving problems occur is considered the steady state, even though either `atol`, `rtol` or `maxSS` have not been achieved.

9.4.4 infSSstep

`infSSstep` Step size for determining if a constant infusion has reached steady state. By default this is large value, 420.

9.4.5 **ssAtol**

`ssAtol` Steady state atol convergence factor. Can be a vector based on each state.

9.4.6 **ssRtol**

`ssRtol` Steady state rtol convergence factor. Can be a vector based on each state.

9.5 **RxODE numeric stability options**

9.5.1 **maxAtolRtolFactor**

`maxAtolRtolFactor` The maximum atol/rtol that FOCEi and other routines may adjust to. By default 0.1

9.5.2 **stateTrim**

`stateTrim` When amounts/concentrations in one of the states are above this value, trim them to be this value. By default Inf. Also trims to -stateTrim for large negative amounts/concentrations. If you want to trim between a range say $c(0, 2000000)$ you may specify 2 values with a lower and upper range to make sure all state values are in the reasonable range.

9.5.3 **safeZero**

`safeZero` Use safe zero divide and log routines. By default this is turned on but you may turn it off if you wish.

9.5.4 **sumType**

`sumType` Sum type to use for `sum()` in RxODE code blocks.

`pairwise` uses the pairwise sum (fast, default)

`fsum` uses Python's `fsum` function (most accurate)

`kahan` uses Kahan correction

`neumaier` uses Neumaier correction

`c` uses no correction: default/native summing

9.5.5 prodType

prodType Product to use for prod() in RxODE blocks

long double converts to long double, performs the multiplication and then converts back.

double uses the standard double scale for multiplication.

9.5.6 maxwhile

maxwhile represents the maximum times a while loop is evaluated before exiting. By default this is 100000

9.5.7 transitAbs

transitAbs boolean indicating if this is a transit compartment absorption

9.6 Linear compartment model sensitivity options

9.6.1 sensType

sensType Sensitivity type for linCmt() model:

advan Use the direct advan solutions

autodiff Use the autodiff advan solutions

forward Use forward difference solutions

central Use central differences

9.6.2 linDiff

linDiff This gives the linear difference amount for all the types of linear compartment model parameters where sensitivities are not calculated. The named components of this numeric vector are:

- "lag" Central compartment lag
- "f" Central compartment bioavailability
- "rate" Central compartment modeled rate
- "dur" Central compartment modeled duration
- "lag2" Depot compartment lag
- "f2" Depot compartment bioavailability

- "rate2" Depot compartment modeled rate
- "dur2" Depot compartment modeled duration

9.6.3 linDiffCentral

`linDiffCentral` This gives the which parameters use central differences for the linear compartment model parameters. The are the same components as `linDiff`

9.7 Covariate Solving Options

9.7.1 iCov

`iCov` A data frame of individual non-time varying covariates to combine with the `params` to form a parameter `data.frame`.

9.7.2 covsInterpolation

`covsInterpolation` specifies the interpolation method for time-varying covariates. When solving ODEs it often samples times outside the sampling time specified in events. When this happens, the time varying covariates are interpolated. Currently this can be:

- "linear" interpolation, which interpolates the covariate by solving the line between the observed covariates and extrapolating the new covariate value.
- "constant" – Last observation carried forward (the default).
- "NOCB" – Next Observation Carried Backward. This is the same method that NONMEM uses.
- "midpoint" Last observation carried forward to midpoint; Next observation carried backward to midpoint.

9.7.3 addCov

`addCov` A boolean indicating if covariates should be added to the output matrix or data frame. By default this is disabled.

9.8 Simulation options

9.8.1 seed

`seed` an object specifying if and how the random number generator should be initialized

9.8.2 nsim

`nsim` represents the number of simulations. For RxODE, if you supply single subject event tables (created with `[eventTable()]`)

9.8.3 thetaMat

`thetaMat` Named theta matrix.

9.8.4 thetaLower

`thetaLower` Lower bounds for simulated population parameter variability (by default `-Inf`)

9.8.5 thetaUpper

`thetaUpper` Upper bounds for simulated population unexplained variability (by default `Inf`)

9.8.6 thetaDf

`thetaDf` The degrees of freedom of a t-distribution for simulation. By default this is `NULL` which is equivalent to `Inf` degrees, or to simulate from a normal distribution instead of a t-distribution.

9.8.7 thetaIsChol

`thetaIsChol` Indicates if the `theta` supplied is a Cholesky decomposed matrix instead of the traditional symmetric matrix.

9.8.8 nStud

nStud Number virtual studies to characterize uncertainty in estimated parameters.

9.8.9 omega

omega Estimate of Covariance matrix. When omega is a list, assume it is a block matrix and convert it to a full matrix for simulations.

9.8.10 omegaIsChol

omegaIsChol Indicates if the omega supplied is a Cholesky decomposed matrix instead of the traditional symmetric matrix.

9.8.11 omegaSeparation

omegaSeparation Omega separation strategy

Tells the type of separation strategy when simulating covariance with parameter uncertainty with standard deviations modeled in the thetaMat matrix.

- "lkj" simulates the correlation matrix from the rLKJ1 matrix with the distribution parameter eta equal to the degrees of freedom nu by $(nu-1)/2$
- "separation" simulates from the identity inverse Wishart covariance matrix with nu degrees of freedom. This is then converted to a covariance matrix and augmented with the modeled standard deviations. While computationally more complex than the "lkj" prior, it performs better when the covariance matrix size is greater or equal to 10
- "auto" chooses "lkj" when the dimension of the matrix is less than 10 and "separation" when greater than equal to 10.

9.8.12 omegaXform

omegaXform When taking omega values from the thetaMat simulations (using the separation strategy for covariance simulation), how should the thetaMat values be turned into standard deviation values:

- identity This is when standard deviation values are directly modeled by the params and thetaMat matrix

- **variance** This is when the `params` and `thetaMat` simulates the variance that are directly modeled by the `thetaMat` matrix
- **log** This is when the `params` and `thetaMat` simulates $\log(sd)$
- **nlmixrSqrt** This is when the `params` and `thetaMat` simulates the inverse cholesky decomposed matrix with the x^2 modeled along the diagonal. This only works with a diagonal matrix.
- **nlmixrLog** This is when the `params` and `thetaMat` simulates the inverse cholesky decomposed matrix with the $\exp(x^2)$ along the diagonal. This only works with a diagonal matrix.
- **nlmixrIdentity** This is when the `params` and `thetaMat` simulates the inverse cholesky decomposed matrix. This only works with a diagonal matrix.

9.8.13 **omegaLower**

`omegaLower` Lower bounds for simulated ETAs (by default `-Inf`)

9.8.14 **omegaUpper**

`omegaUpper` Upper bounds for simulated ETAs (by default `Inf`)

9.8.15 **omegaDf**

`omegaDf` The degrees of freedom of a t-distribution for simulation. By default this is `NULL` which is equivalent to `Inf` degrees, or to simulate from a normal distribution instead of a t-distribution.

9.8.16 **nSub**

`nSub` Number between subject variabilities (ETAs) simulated for every realization of the parameters.

9.8.17 **dfSub**

`dfSub` Degrees of freedom to sample the between subject variability matrix from the inverse Wishart distribution (scaled) or scaled inverse chi squared distribution.

9.8.18 **sigma**

sigma Named sigma covariance or Cholesky decomposition of a covariance matrix. The names of the columns indicate parameters that are simulated. These are simulated for every observation in the solved system.

9.8.19 **sigmaLower**

sigmaLower Lower bounds for simulated unexplained variability (by default -Inf)

9.8.20 **sigmaUpper**

sigmaUpper Upper bounds for simulated unexplained variability (by default Inf)

9.8.21 **sigmaXform**

sigmaXform When taking **sigma** values from the **thetaMat** simulations (using the separation strategy for covariance simulation), how should the **thetaMat** values be turned into standard deviation values:

- **identity** This is when standard deviation values are directly modeled by the **params** and **thetaMat** matrix
- **variance** This is when the **params** and **thetaMat** simulates the variance that are directly modeled by the **thetaMat** matrix
- **log** This is when the **params** and **thetaMat** simulates $\log(sd)$
- **nlmixrSqrt** This is when the **params** and **thetaMat** simulates the inverse cholesky decomposed matrix with the x^2 modeled along the diagonal. This only works with a diagonal matrix.
- **nlmixrLog** This is when the **params** and **thetaMat** simulates the inverse cholesky decomposed matrix with the $\exp(x^2)$ along the diagonal. This only works with a diagonal matrix.
- **nlmixrIdentity** This is when the **params** and **thetaMat** simulates the inverse cholesky decomposed matrix. This only works with a diagonal matrix.

9.8.22 **sigmaDf**

sigmaDf Degrees of freedom of the sigma t-distribution. By default it is equivalent to Inf, or a normal distribution.

9.8.23 sigmaIsChol

`sigmaIsChol` Boolean indicating if the sigma is in the Cholesky decomposition instead of a symmetric covariance

9.8.24 sigmaSeparation

`sigmaSeparation` separation strategy for sigma;

Tells the type of separation strategy when simulating covariance with parameter uncertainty with standard deviations modeled in the `thetaMat` matrix.

- "lkj" simulates the correlation matrix from the `rLKJ1` matrix with the distribution parameter `eta` equal to the degrees of freedom `nu` by $(nu-1)/2$
- "separation" simulates from the identity inverse Wishart covariance matrix with `nu` degrees of freedom. This is then converted to a covariance matrix and augmented with the modeled standard deviations. While computationally more complex than the "lkj" prior, it performs better when the covariance matrix size is greater or equal to 10
- "auto" chooses "lkj" when the dimension of the matrix is less than 10 and "separation" when greater than equal to 10.

9.8.25 dfObs

`dfObs` Degrees of freedom to sample the unexplained variability matrix from the inverse Wishart distribution (scaled) or scaled inverse chi squared distribution.

9.8.26 resample

`resample` A character vector of model variables to resample from the input dataset; This sampling is done with replacement. When `NULL` or `FALSE` no resampling is done. When `TRUE` resampling is done on all covariates in the input dataset

9.8.27 resampleID

`resampleID` boolean representing if the resampling should be done on an individual basis `TRUE` (ie. a whole patient is selected) or each covariate is resampled independent of the subject identifier `FALSE`. When `resampleID=TRUE` correlations of parameters are retained, where as when `resampleID=FALSE` ignores patient covariate correlations. Hence the default is `resampleID=TRUE`.

9.9 RxODE output options

9.9.1 returnType

returnType This tells what type of object is returned. The currently supported types are:

- "rxSolve" (default) will return a reactive data frame that can change easily change different pieces of the solve and update the data frame. This is the currently standard solving method in RxODE, is used for `rxSolve(object, ...)`, `solve(object, ...)`,
- "data.frame" – returns a plain, non-reactive data frame; Currently very slightly faster than `returnType="matrix"`
- "matrix" – returns a plain matrix with column names attached to the solved object. This is what is used `object$run` as well as `object$solve`
- "data.table" – returns a `data.table`; The `data.table` is created by reference (ie `setDt()`), which should be fast.
- "tbl" or "tibble" returns a tibble format.

9.9.2 addDosing

addDosing Boolean indicating if the solve should add RxODE EVID and related columns. This will also include dosing information and estimates at the doses. By default, RxODE only includes estimates at the observations. (default FALSE). When `addDosing` is NULL, only include `EVID=0` on solve and exclude any model-times or `EVID=2`. If `addDosing` is NA the classic RxODE EVID events are returned. When `addDosing` is TRUE add the event information in NONMEM-style format; If `subsetNonmem=FALSE` RxODE will also include extra event types (EVID) for ending infusion and modeled times:

- `EVID=-1` when the modeled rate infusions are turned off (matches `rate=-1`)
- `EVID=-2` When the modeled duration infusions are turned off (matches `rate=-2`)
- `EVID=-10` When the specified rate infusions are turned off (matches `rate>0`)
- `EVID=-20` When the specified dur infusions are turned off (matches `dur>0`)
- `EVID=101, 102, 103, ...` Modeled time where 101 is the first model time, 102 is the second etc.

9.9.3 keep

`keep` Columns to keep from either the input dataset or the `iCov` dataset. With the `iCov` dataset, the column is kept once per line. For the input dataset, if any records are added to the data LOCF (Last Observation Carried forward) imputation is performed.

9.9.4 drop

`drop` Columns to drop from the output

9.9.5 idFactor

`idFactor` This boolean indicates if original ID values should be maintained. This changes the default sequentially ordered ID to a factor with the original ID values in the original dataset. By default this is enabled.

9.9.6 subsetNonmem

`subsetNonmem` subset to NONMEM compatible EVIDs only. By default TRUE.

9.9.7 matrix

`matrix` A boolean indicating if a matrix should be returned instead of the RxODE's solved object.

9.9.8 scale

`scale` a numeric named vector with scaling for ode parameters of the system. The names must correspond to the parameter identifiers in the ODE specification. Each of the ODE variables will be divided by the scaling factor. For example `scale=c(center=2)` will divide the center ODE variable by 2.

9.9.9 amountUnits

`amountUnits` This supplies the dose units of a data frame supplied instead of an event table. This is for importing the data as an RxODE event table.

9.9.10 timeUnits

`timeUnits` This supplies the time units of a data frame supplied instead of an event table. This is for importing the data as an RxODE event table.

9.9.11 theta

`theta` A vector of parameters that will be named THETA\[#\] and added to parameters

9.9.12 eta

`eta` A vector of parameters that will be named ETA\[#\] and added to parameters

9.9.13 from

`from` When there is no observations in the event table, start observations at this value. By default this is zero.

9.9.14 to

`to` When there is no observations in the event table, end observations at this value. By default this is 24 + maximum dose time.

9.9.15 length.out

`length.out` The number of observations to create if there isn't any observations in the event table. By default this is 200.

9.9.16 by

`by` When there are no observations in the event table, this is the amount to increment for the observations between `from` and `to`.

9.9.17 warnIdSort

`warnIdSort` Warn if the ID is not present and RxODE assumes the order of the parameters/iCov are the same as the order of the parameters in the input dataset.

9.9.18 warnDrop

warnDrop Warn if column(s) were supposed to be dropped, but were not present.

9.10 Internal RxODE options

9.10.1 nDisplayProgress

nDisplayProgress An integer indicating the minimum number of c-based solves before a progress bar is shown. By default this is 10,000.

9.10.2 ...

... Other arguments including scaling factors for each compartment. This includes $S\#$ = numeric will scale a compartment # by a dividing the compartment amount by the scale factor, like NONMEM.

9.10.3 a

a when using `solve()`, this is equivalent to the `object` argument. If you specify `object` later in the argument list it overwrites this parameter.

9.10.4 b

b when using `solve()`, this is equivalent to the `params` argument. If you specify `params` as a named argument, this overwrites the output

9.10.5 updateObject

updateObject This is an internally used flag to update the RxODE solved object (when supplying an RxODE solved object) as well as returning a new object. You probably should not modify it's FALSE default unless you are willing to have unexpected results.

9.11 Parallel/Threaded Solve

9.11.1 **cores**

cores Number of cores used in parallel ODE solving. This is equivalent to calling `[setRxThreads()]`

9.11.2 **nCoresRV**

nCoresRV Number of cores used for the simulation of the sigma variables. By default this is 1. To reproduce the results you need to run on the same platform with the same number of cores. This is the reason this is set to be one, regardless of what the number of cores are used in threaded ODE solving.

Chapter 10

RxODE output

10.1 Using RxODE data frames

10.1.1 Creating an interactive data frame

RxODE supports returning a solved object that is a modified data-frame. This is done by the `predict()`, `solve()`, or `rxSolve()` methods.

```
library(RxODE)
library(units)

### Setup example model
mod1 <- RxODE({
  C2 = centr/V2;
  C3 = peri/V3;
  d/dt(depot) = -KA*depot;
  d/dt(centr) = KA*depot - CL*C2 - Q*C2 + Q*C3;
  d/dt(peri) = Q*C2 - Q*C3;
  d/dt(eff) = Kin - Kout*(1-C2/(EC50+C2))*eff;
})

### Seup parameters and initial conditions

theta <-
  c(KA=2.94E-01, CL=1.86E+01, V2=4.02E+01, # central
    Q=1.05E+01, V3=2.97E+02, # peripheral
    Kin=1, Kout=1, EC50=200) # effects

inits <- c(eff=1)
```

```

### Setup dosing event information
ev <- eventTable(amount.units="mg", time.units="hours") %>%
  add.dosing(dose=10000, nbr.doses=10, dosing.interval=12) %>%
  add.dosing(dose=20000, nbr.doses=5, start.time=120,
    dosing.interval=24) %>%
  add.sampling(0:240);

### Now solve
x <- predict(mod1,theta, ev, inits)
print(x)

```

```

#> ----- Solved RxODE object -----
#> -- Parameters ($params): -----
#>      V2      V3      KA      CL      Q      Kin      Kout      EC50

#> # ... with 235 more rows
#> -----
```

10.1.2 RxODE solved object properties

10.1.3 Using the solved object as a simple data frame

The solved object acts as a `data.frame` or `tbl` that can be filtered by `dplyr`. For example you could filter it easily.

```
library(dplyr)

#>
#> Attaching package: 'dplyr'

#> The following objects are masked from 'package:stats':
#>
#>     filter, lag

#> The following objects are masked from 'package:base':
#>
#>     intersect, setdiff, setequal, union

### You can drop units for comparisons and filtering
x <- mod1 %>% solve(theta, ev, inits) %>%
  drop_units %>% filter(time <= 3) %>% as.tbl

#> Warning: `as.tbl()` was deprecated in dplyr 1.0.0.
#> Please use `tibble::as_tibble()` instead.

### or keep them and compare with the proper units.
x <- mod1 %>% solve(theta, ev, inits) %>%
  filter(time <= set_units(3, hr)) %>% as.tbl
x

#> # A tibble: 4 x 7
#>   time      C2      C3  depot centr  peri  eff
#>   [h] <dbl> <dbl> <dbl> <dbl> <dbl> <dbl>
#> 1     0     0     0  10000     0     0     1
#> 2     1  44.4  0.920  7453. 1784.  273.  1.08
#> 3     2  54.9  2.67   5554. 2206.  794.  1.18
#> 4     3  51.9  4.46   4140. 2087. 1324.  1.23
```

10.2 Updating the data-set interactively

However it isn't just a simple data object. You can use the solved object to update parameters on the fly, or even change the sampling time.

First we need to recreate the original solved system:

```
x <- mod1 %>% solve(theta,ev,inits);
print(x)
```

```
#> ----- Solved RxODE object -----
#> -- Parameters ($params): -----
#>      V2      V3      KA      CL      Q      Kin      Kout      EC50
#> 40.200 297.000  0.294 18.600 10.500  1.000  1.000 200.000
#> -- Initial Conditions ($inits): -----
#> depot centr  peri  eff
#>    0      0      0    1
#> -- First part of data (object): -----
#> # A tibble: 241 x 7
#>   time    C2    C3  depot centr  peri  eff
#>   [h] <dbl> <dbl> <dbl> <dbl> <dbl> <dbl>
#> 1     0     0     0  10000     0     0     1
#> 2     1  44.4  0.920  7453. 1784.  273.  1.08
#> 3     2  54.9  2.67   5554. 2206.  794.  1.18
#> 4     3  51.9  4.46   4140. 2087. 1324.  1.23
#> 5     4  44.5  5.98   3085. 1789. 1776.  1.23
#> 6     5  36.5  7.18   2299. 1467. 2132.  1.21
#> # ... with 235 more rows
#> -----
```

10.2.1 Modifying initial conditions

To examine or change initial conditions, you can use the syntax `cmt.0`, `cmt0`, or `cmt_0`. In the case of the `eff` compartment defined by the model, this is:

```
x$eff0
```

```
#> [1] 1
```

which shows the initial condition of the effect compartment. If you wished to change this initial condition to 2, this can be done easily by:

```
x$eff0 <- 2
print(x)
```

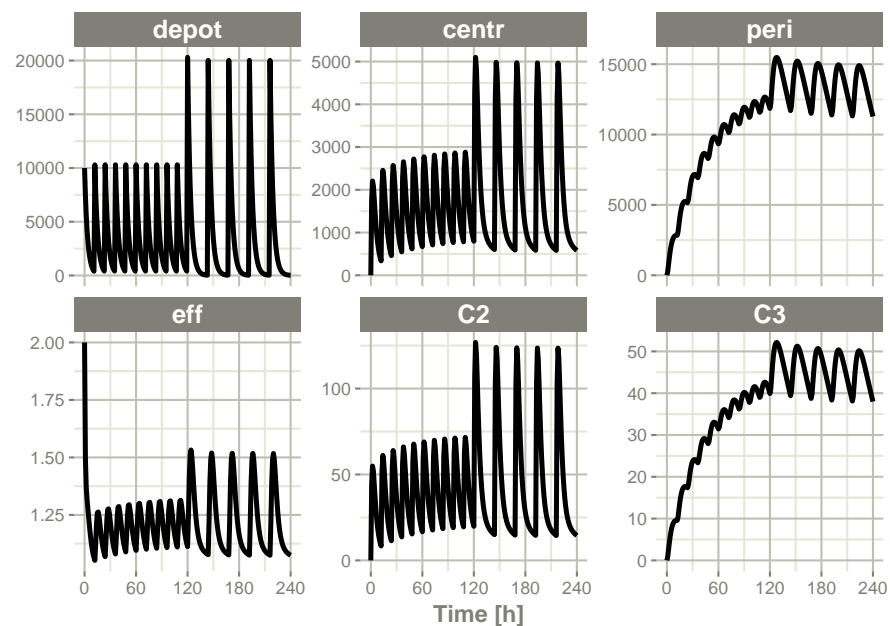

```
#> ----- Solved RxODE object -----
#> -- Parameters ($params): -----
#>      V2      V3      KA      CL      Q      Kin      Kout      EC50
#> 40.200 297.000  0.294 18.600 10.500  1.000  1.000 200.000
```

```

#> -- Initial Conditions ($inits): -----
#> depot centr peri eff
#>    0      0      0      2
#> -- First part of data (object): -----
#> # A tibble: 241 x 7
#>   time    C2    C3 depot centr  peri  eff
#>   [h] <dbl> <dbl> <dbl> <dbl> <dbl> <dbl>
#> 1     0     0     0 10000     0     0     2
#> 2     1  44.4  0.920  7453. 1784.  273.  1.50
#> 3     2  54.9  2.67  5554. 2206.  794.  1.37
#> 4     3  51.9  4.46  4140. 2087. 1324.  1.31
#> 5     4  44.5  5.98  3085. 1789. 1776.  1.27
#> 6     5  36.5  7.18  2299. 1467. 2132.  1.23
#> # ... with 235 more rows
#> -----

```

```
plot(x)
```

10.2.2 Modifying observation times for RxODE

Notice that the initial effect is now 2.

You can also change the sampling times easily by this method by changing `t` or `time`. For example:

```
x$t <- seq(0,5,length.out=20)
print(x)
```

```
#> ----- Solved RxODE object -----
#> -- Parameters ($params): -----
#>      V2      V3      KA      CL      Q      Kin      Kout      EC50
#> 40.200 297.000 0.294 18.600 10.500 1.000 1.000 200.000
#> -- Initial Conditions ($inits): -----
#> depot centr peri eff
#>    0     0     0     2
#> -- First part of data (object): -----
#> # A tibble: 20 x 7
#>       time      C2      C3 depot centr peri eff
#>       [h] <dbl> <dbl> <dbl> <dbl> <dbl> <dbl>
#> 1 0.0000000  0  0    10000  0  0  2
#> 2 0.2631579 16.8 0.0817 9255. 677. 24.3 1.79
#> 3 0.5263158 29.5 0.299 8566. 1187. 88.7 1.65
#> 4 0.7894737 38.9 0.615 7929. 1562. 183. 1.55
#> 5 1.0526316 45.5 1.00 7338. 1830. 298. 1.49
#> 6 1.3157895 50.1 1.44 6792. 2013. 427. 1.44
#> # ... with 14 more rows
#> -----
```

```
plot(x)
```

10.2.3 Modifying simulation parameters

You can also access or change parameters by the `$` operator. For example, accessing `KA` can be done by:

```
x$KA
```

```
#> [1] 0.294
```

And you may change it by assigning it to a new value.

```
x$KA <- 1
print(x)
```

```
#> ----- Solved RxODE object -----
#> -- Parameters ($params): -----
#>   V2   V3   KA   CL   Q   Kin  Kout  EC50
#> 40.2 297.0  1.0 18.6 10.5  1.0   1.0 200.0
#> -- Initial Conditions ($inits): -----
#> depot centr  peri  eff
#>    0     0     0    2
#> -- First part of data (object): -----
#> # A tibble: 20 x 7
#>       time      C2      C3  depot centr    peri    eff
#>   [h] <dbl> <dbl> <dbl> <dbl> <dbl> <dbl>
#> 1 0.0000000    0    0  10000     0     0     2
#> 2 0.2631579  52.2 0.261  7686. 2098.   77.6   1.82
#> 3 0.5263158  83.3 0.900  5908. 3348.   267.   1.74
#> 4 0.7894737  99.8 1.75   4541. 4010.   519.   1.69
#> 5 1.0526316 106.  2.69   3490. 4273.   800.   1.67
#> 6 1.3157895 106.  3.66   2683. 4272.  1086.   1.64
#> # ... with 14 more rows
#> -----
```

```
plot(x)
```

You can access/change all the parameters, initialization(s) or events with the `$params`, `$inits`, `$events` accessor syntax, similar to what is used above.

This syntax makes it easy to update and explore the effect of various parameters on the solved object.

Chapter 11

Simulation

Chapter 12

Examples

This section is for example models to get you started in common simulation scenarios.

12.1 Weight based dosing

This is an example model for weight based dosing of daptomycin. Daptomycin is a cyclic lipopeptide antibiotic from fermented *Streptomyces roseosporus*.

There are 3 stages for weight-based dosing simulations: - Create RxODE model - Simulate Covariates - Create event table with weight-based dosing (merged back to covariates)

12.1.1 Creating a 2-compartment model in RxODE

```
library(RxODE)

## Note the time covariate is not included in the simulation
m1 <- RxODE({
  CL ~ (1-0.2*SEX)*(0.807+0.00514*(CRCL-91.2))*exp(eta.cl)
  V1 ~ 4.8*exp(eta.v1)
  Q ~ (3.46+0.0593*(WT-75.1))*exp(eta.q);
  V2 ~ 1.93*(3.13+0.0458*(WT-75.1))*exp(eta.v2)
  A1 ~ centr;
  A2 ~ peri;
  d/dt(centr) ~ - A1*(CL/V1 + Q/V1) + A2*Q/V2;
  d/dt(peri) ~ A1*Q/V1 - A2*Q/V2;
```

```
DV = centr / V1 * (1 + prop.err)
})
```

12.1.2 Simulating Covariates

This simulation correlates age, sex, and weight. Since we will be using weight based dosing, this needs to be simulated first

```
set.seed(42)
library(dplyr)
nsub=30
### Simulate Weight based on age and gender
AGE<-round(runif(nsub,min=18,max=70))
SEX<-round(runif(nsub,min=0,max=1))
HTm<-round(rnorm(nsub,176.3,0.17*sqrt(4482)),digits=1)
HTf<-round(rnorm(nsub,162.2,0.16*sqrt(4857)),digits=1)
WTm<-round(exp(3.28+1.92*log(HTm/100))*exp(rnorm(nsub,0,0.14)),digits=1)
WTf<-round(exp(3.49+1.45*log(HTf/100))*exp(rnorm(nsub,0,0.17)),digits=1)
WT<-ifelse(SEX==1,WTf,WTm)
CRCL<-round(runif(nsub,30,140))
## id is in lower case to match the event table
cov.df <- tibble(id=seq_along(AGE), AGE=AGE, SEX=SEX, WT=WT, CRCL=CRCL)
print(cov.df)
```

```
#> # A tibble: 30 x 5
#>       id  AGE  SEX    WT  CRCL
#>   <int> <dbl> <dbl> <dbl> <dbl>
#> 1     1    66     1  49.4    83
#> 2     2    67     1  52.5    79
#> 3     3    33     0  97.9    37
#> 4     4    61     1  63.8    66
#> 5     5    51     0  71.8   127
#> 6     6    45     1  69.6   132
#> 7     7    56     0  61      73
#> 8     8    25     0  57.7    47
#> 9     9    52     1  58.7    65
#> 10    10    55     1  73.1    64
#> # ... with 20 more rows
```

12.1.3 Creating weight based event table

```

s<-c(0,0.25,0.5,0.75,1,1.5,seq(2,24,by=1))
s <- lapply(s, function(x){.x <- 0.1 * x; c(x - .x, x + .x)})

e <- et() %>%
  ## Specify the id and weight based dosing from covariate data.frame
  ## This requires RxODE XXX
  et(id=cov.df$id, amt=6*cov.df$WT, rate=6 * cov.df$WT) %>%
  ## Sampling is added for each ID
  et(s) %>%
  as.data.frame %>%
  ## Merge the event table with the covariate information
  merge(cov.df, by="id") %>%
  as_tibble

e

```

```

#> # A tibble: 900 x 12
#>       id   low time   high cmt      amt  rate evid  AGE  SEX  WT  CRCL
#>   <int> <dbl> <dbl> <dbl> <chr>   <dbl> <dbl> <int> <dbl> <dbl> <dbl> <dbl>
#> 1     1  0     0     0  (obs)    NA    NA     0    66     1  49.4    83
#> 2     1 NA     0    NA  (default) 296.  296.    1    66     1  49.4    83
#> 3     1 0.225 0.246 0.275 (obs)    NA    NA     0    66     1  49.4    83
#> 4     1 0.45  0.516 0.55  (obs)    NA    NA     0    66     1  49.4    83
#> 5     1 0.675 0.729 0.825 (obs)    NA    NA     0    66     1  49.4    83
#> 6     1 0.9   0.921 1.1   (obs)    NA    NA     0    66     1  49.4    83
#> 7     1 1.35  1.42  1.65 (obs)    NA    NA     0    66     1  49.4    83
#> 8     1 1.8   1.82  2.2   (obs)    NA    NA     0    66     1  49.4    83
#> 9     1 2.7   2.97  3.3   (obs)    NA    NA     0    66     1  49.4    83
#> 10    1 3.6   3.87  4.4   (obs)    NA    NA     0    66     1  49.4    83
#> # ... with 890 more rows

```

12.1.4 Solving Daptomycin simulation

```

data <- rxSolve(m1, e,
  ## Lotri uses lower-triangular matrix rep. for named matrix
  omega=lotri(eta.cl ~ .306,
    eta.q ~0.0652,
    eta.v1 ~.567,
    eta.v2 ~ .191),
  sigma=lotri(prop.err ~ 0.15),
  addDosing = TRUE, addCov = TRUE)

```

```
print(data)
```

```
#> ----- Solved RxODE object -----
#> -- Parameters ($params): -----

12.1.5 Daptomycin Reference

This weight-based simulation is adapted from the Daptomycin article below:

Dvorchik B, Arbeit RD, Chung J, Liu S, Knebel W, Kastrissios H. Population pharmacokinetics of daptomycin. *Antimicrob Agents Chemother* 2004; 48: 2799-2807. doi:(10.1128/AAC.48.8.2799-2807.2004)[<https://dx.doi.org/10.1128/AAC.48.8.2799-2807.2004>]

This simulation example was made available from the work of Sherwin Sy with modifications by Matthew Fidler

12.2 Inter-occasion and other nesting examples

More than one level of nesting is possible in RxODE; In this example we will be using the following uncertainties and sources of variability:

	Level	Variable	Matrix specified	Integrated Matrix
Model uncertainty		NA	thetaMat	thetaMat
Investigator		inv.Cl, inv.Ka	omega	theta
Subject		eta.Cl, eta.Ka	omega	omega
Eye		eye.Cl, eye.Ka	omega	omega

	Level	Variable	Matrix specified	Integrated Matrix
	Occasion	iov.Cl, occ.Ka	omega	omega
Unexplained Concentration		prop.sd	sigma	sigma
Unexplained Effect		add.sd	sigma	sigma

12.2.1 Event table

This event table contains nesting variables:

- inv: investigator id
- id: subject id
- eye: eye id (left or right)
- occ: occasion

```
library(RxODE)
library(dplyr)

et(amountUnits="mg", timeUnits="hours") %>%
  et(amt=10000, addl=9, ii=12, cmt="depot") %>%
  et(time=120, amt=2000, addl=4, ii=14, cmt="depot") %>%
  et(seq(0, 240, by=4)) %>% # Assumes sampling when there is no dosing information
  et(seq(0, 240, by=4) + 0.1) %>% ## adds 0.1 for separate eye
  et(id=1:20) %>%
  ## Add an occasion per dose
  mutate(occ=cumsum(!is.na(amt))) %>%
  mutate(occ=ifelse(occ == 0, 1, occ)) %>%
  mutate(occ=2- occ %% 2) %>%
  mutate(eye=ifelse(round(time) == time, 1, 2)) %>%
  mutate(inv=ifelse(id < 10, 1, 2)) %>% as_tibble ->
  ev
```

12.2.2 RxODE model

This creates the RxODE model with multi-level nesting. Note the variables inv.Cl, inv.Ka, eta.Cl etc; You only need one variable for each level of nesting.

```
mod <- RxODE({
  ## Clearance with individuals
  eff(0) = 1
  C2 = centr/V2*(1+prop.sd);
  C3 = peri/V3;
  CL = TC1*exp(eta.Cl + eye.Cl + iov.Cl + inv.Cl)
```

```

KA = TKA * exp(eta.Ka + eye.Ka + iov.Cl + inv.Ka)
d/dt(depot) = -KA*depot;
d/dt(centr) = KA*depot - CL*C2 - Q*C2 + Q*C3;
d/dt(peric) = Q*C2 - Q*C3;
d/dt(ef) = Kin - Kout*(1-C2/(EC50+C2))*ef;
ef0 = ef + add.sd
})

```

12.2.3 Uncertainty in Model parameters

```

theta <- c("TKA"=0.294, "TC1"=18.6, "V2"=40.2,
          "Q"=10.5, "V3"=297, "Kin"=1, "Kout"=1, "EC50"=200)

## Creating covariance matrix
tmp <- matrix(rnorm(8^2), 8, 8)
tMat <- tcrossprod(tmp, tmp) / (8 ^ 2)
dimnames(tMat) <- list(names(theta), names(theta))

tMat

```

```

#>           TKA           TC1           V2           Q           V3

```

12.2.4 Nesting Variability

To specify multiple levels of nesting, you can specify it as a nested `lotri` matrix; When using this approach you use the condition operator `|` to specify what variable nesting occurs on; For the Bayesian simulation we need to specify how much information we have for each parameter; For `RxODE` this is the `nu` parameter.

In this case: - `id, nu=100` or the model came from 100 subjects - `eye, nu=200` or the model came from 200 eyes - `occ, nu=200` or the model came from 200 occasions - `inv, nu=10` or the model came from 10 investigators

To specify this in `lotri` you can use `| var(nu=X)`, or:

```
omega <- lotri(lotri(eta.Cl ~ 0.1,
                    eta.Ka ~ 0.1) | id(nu=100),
              lotri(eye.Cl ~ 0.05,
                    eye.Ka ~ 0.05) | eye(nu=200),
              lotri(iov.Cl ~ 0.01,
                    iov.Ka ~ 0.01) | occ(nu=200),
              lotri(inv.Cl ~ 0.02,
                    inv.Ka ~ 0.02) | inv(nu=10))
omega
```

```
#> $id
#>      eta.Cl eta.Ka
#> eta.Cl    0.1    0.0
#> eta.Ka    0.0    0.1
#>
#> $eye
#>      eye.Cl eye.Ka
#> eye.Cl    0.05    0.00
#> eye.Ka    0.00    0.05
#>
#> $occ
#>      iov.Cl iov.Ka
#> iov.Cl    0.01    0.00
#> iov.Ka    0.00    0.01
#>
#> $inv
#>      inv.Cl inv.Ka
#> inv.Cl    0.02    0.00
#> inv.Ka    0.00    0.02
#>
#> Properties: nu
```

12.2.5 Unexplained variability

The last piece of variability to specify is the unexplained variability

```
sigma <- lotri(prop.sd ~ .25,
              add.sd~ 0.125)
```

12.2.6 Solving the problem

```
s <- rxSolve(mod, theta, ev,
            thetaMat=tMat, omega=omega,
            sigma=sigma, sigmaDf=400,
            nStud=400)
```

```
#> unhandled error message: EE:[lsoda] 70000 steps taken before reaching tout
#>  @(lsoda.c:748
```

```
#> Warning: some ID(s) could not solve the ODEs correctly; These values are
#> replaced with 'NA'
```

```
print(s)
```

```

```

There are multiple investigators in a study; Each investigator has a number of individuals enrolled at their site. RxODE automatically determines the number of investigators and then will simulate an effect for each investigator. With the output, `inv.Cl(inv==1)` will be the `inv.Cl` for investigator 1, `inv.Cl(inv==2)` will be the `inv.Cl` for investigator 2, etc.

`inv.Cl(inv==1)`, `inv.Cl(inv==2)`, etc will be simulated for each study and then combined to form the between investigator variability. In equation form these represent the following:

$$\text{inv.Cl} = (\text{inv} == 1) * \text{inv.Cl}(\text{inv}==1) + (\text{inv} == 2) * \text{inv.Cl}(\text{inv}==2)$$

If you look at the simulated parameters you can see `inv.Cl(inv==1)` and `inv.Cl(inv==2)` are in the `s$params`; They are the same for each study:

```
print(head(s$params))
```

```

#>   sim.id id inv.Cl(inv==1) inv.Cl(inv==2) inv.Ka(inv==1) inv.Ka(inv==2)
#> 1     1  1  0.01864161    0.1159198    0.1878234    -0.292727

```

For between eye variability and between occasion variability each individual simulates a number of variables that become the between eye and between occasion variability; In the case of the eye:

```
eye.Cl = (eye == 1) * `eye.Cl(eye==1)` + (eye == 2) * `eye.Cl(eye==2)`
```

So when you look the simulation each of these variables (ie `eye.Cl(eye==1)`, `eye.Cl(eye==2)`, etc) they change for each individual and when combined make the between eye variability or the between occasion variability that can be seen in some pharmacometric models.

Chapter 13

Advanced & Miscellaneous Topics

This covers advanced or miscellaneous topics in RxODE

13.1 Using RxODE with a pipeline

13.1.1 Setting up the RxODE model for the pipeline

In this example we will show how to use RxODE in a simple pipeline.

We can start with a model that can be used for the different simulation workflows that RxODE can handle:

```
library(RxODE)

Ribba2012 <- RxODE({
  k = 100

  tkde = 0.24
  eta.tkde = 0
  kde ~ tkde*exp(eta.tkde)

  tkpq = 0.0295
  eta.kpq = 0
  kpq ~ tkpq * exp(eta.kpq)

  tkqpp = 0.0031
```

```

eta.kqpp = 0
kqpp ~ tkqpp * exp(eta.kqpp)

tlambdap = 0.121
eta.lambdap = 0
lambdap ~ tlambdap*exp(eta.lambdap)

tgamma = 0.729
eta.gamma = 0
gamma ~ tgamma*exp(eta.gamma)

tdeltaqp = 0.00867
eta.deltaqp = 0
deltaqp ~ tdeltaqp*exp(eta.deltaqp)

prop.err <- 0
pstar <- (pt+q+qp)*(1+prop.err)
d/dt(c) = -kde * c
d/dt(pt) = lambdap * pt *(1-pstar/k) + kqpp*qp -
          kpq*pt - gamma*c*kde*pt
d/dt(q) = kpq*pt -gamma*c*kde*q
d/dt(qp) = gamma*c*kde*q - kqpp*qp - deltaqp*qp
#### initial conditions
tpt0 = 7.13
eta.pt0 = 0
pt0 ~ tpt0*exp(eta.pt0)
tq0 = 41.2
eta.q0 = 0
q0 ~ tq0*exp(eta.q0)
pt(0) = pt0
q(0) = q0
})

```

This is a tumor growth model described in Ribba 2012. In this case, we compiled the model into an R object Ribba2012, though in an RxODE simulation pipeline, you do not *have* to assign the compiled model to any object, though I think it makes sense.

13.1.2 Simulating one event table

Simulating a single event table is quite simple:

- You pipe the RxODE simulation object into an event table object by `et()`.

- When the events are completely specified, you simply solve the ODE system with `rxSolve()`.
- In this case you can pipe the output to `plot()` to conveniently view the results.
- Note for the plot we are only selecting the selecting following:
 - `pt` (Proliferative Tissue),
 - `q` (quiescent tissue)
 - `qp` (DNA-Damaged quiescent tissue) and
 - `pstar` (total tumor tissue)

```
Ribba2012 %>% # Use RxODE
  et(time.units="months") %>% # Pipe to a new event table
  et(amt=1, time=50, until=58, ii=1.5) %>% # Add dosing every 1.5 months
  et(0, 250, by=0.5) %>% # Add some sampling times (not required)
  rxSolve() %>% # Solve the simulation
  plot(pt, q, qp, pstar) # Plot it, plotting the variables of interest
```

13.1.3 Simulating multiple subjects from a single event table

13.1.3.1 Simulating with between subject variability

The next sort of simulation that may be useful is simulating multiple patients with the same treatments. In this case, we will use the omega matrix specified by the paper:

```
#### Add CVs from paper for individual simulation
#### Uses exact formula:

lognCv = function(x){log((x/100)^2+1)}

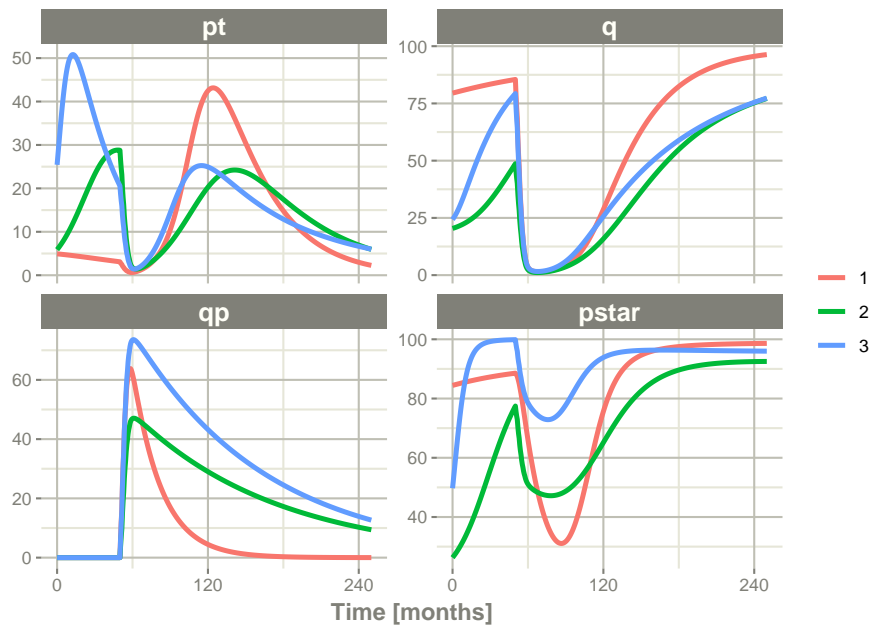

library(lotri)
#### Now create omega matrix
#### I'm using lotri to quickly specify names/diagonals
omega <- lotri(eta.pt0 ~ lognCv(94),
               eta.q0 ~ lognCv(54),
               eta.lambdap ~ lognCv(72),
               eta.kqp ~ lognCv(76),
               eta.qpp ~ lognCv(97),
               eta.deltaqp ~ lognCv(115),
               eta.kde ~ lognCv(70))

omega
```

```
#>           eta.pt0      eta.q0 eta.lambdap   eta.kqp   eta.qpp eta.deltaqp
#> eta.pt0      0.6331848 0.0000000   0.0000000 0.0000000 0.0000000   0.0000000
#> eta.q0      0.0000000 0.2558818   0.0000000 0.0000000 0.0000000   0.0000000
#> eta.lambdap 0.0000000 0.0000000   0.4176571 0.0000000 0.0000000   0.0000000
#> eta.kqp     0.0000000 0.0000000   0.0000000 0.4559047 0.0000000   0.0000000
#> eta.qpp     0.0000000 0.0000000   0.0000000 0.0000000 0.6631518   0.0000000
#> eta.deltaqp 0.0000000 0.0000000   0.0000000 0.0000000 0.0000000   0.8426442
#> eta.kde     0.0000000 0.0000000   0.0000000 0.0000000 0.0000000   0.0000000
#>           eta.kde
#> eta.pt0     0.0000000
#> eta.q0     0.0000000
#> eta.lambdap 0.0000000
#> eta.kqp     0.0000000
#> eta.qpp     0.0000000
#> eta.deltaqp 0.0000000
#> eta.kde     0.3987761
```

With this information, it is easy to simulate 3 subjects from the model-based parameters:

```
set.seed(1089)
Ribba2012 %>% # Use RxODE
  et(time.units="months") %>% # Pipe to a new event table
  et(amt=1, time=50, until=58, ii=1.5) %>% # Add dosing every 1.5 months
  et(0, 250, by=0.5) %>% # Add some sampling times (not required)
  rxSolve(nSub=3, omega=omega) %>% # Solve the simulation
  plot(pt, q, qp, pstar) # Plot it, plotting the variables of interest
```

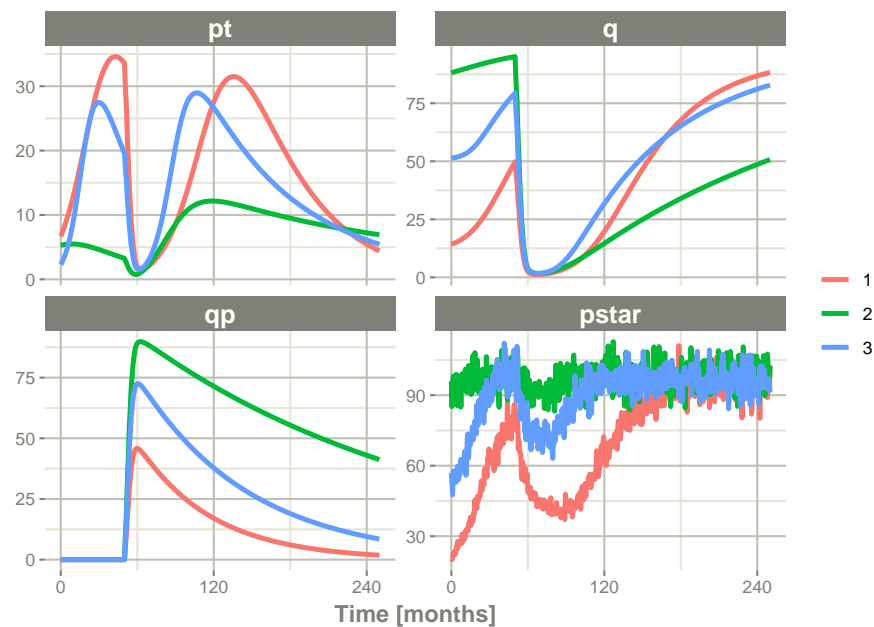

Note there are two different things that were added to this simulation: - nSub to specify how many subjects are in the model - omega to specify the between subject variability.

13.1.3.2 Simulation with unexplained variability

You can even add unexplained variability quite easily:

```
Ribba2012 %>% # Use RxODE
  et(time.units="months") %>% # Pipe to a new event table
  et(amt=1, time=50, until=58, ii=1.5) %>% # Add dosing every 1.5 months
  et(0, 250, by=0.5) %>% # Add some sampling times (not required)
  rxSolve(nSub=3, omega=omega, sigma=lotri(prop.err ~ 0.05^2)) %>% # Solve the simulation
  plot(pt, q, qp, pstar) # Plot it, plotting the variables of interest
```

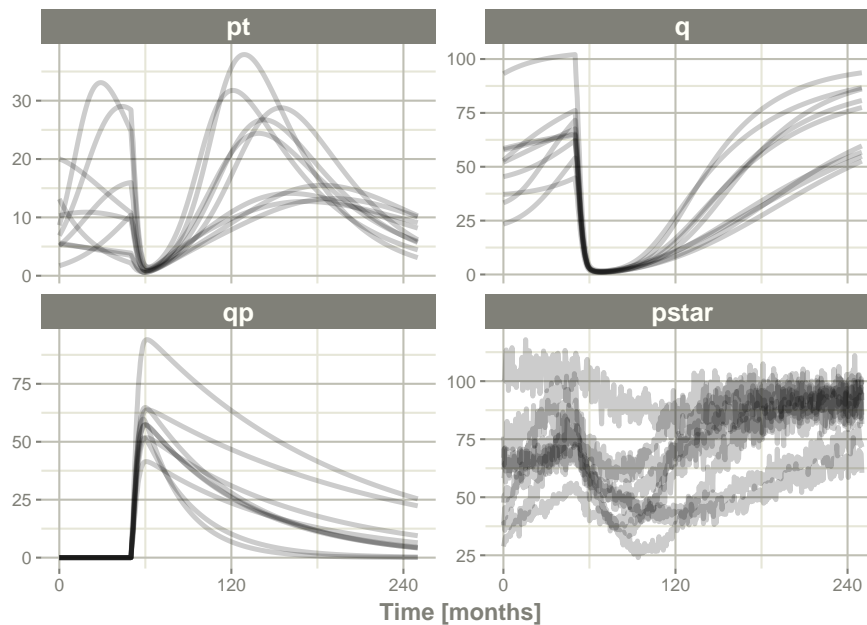

In this case we only added the `sigma` matrix to have unexplained variability on the `pstar` or total tumor tissue.

You can even simulate with uncertainty in the `theta` `omega` and `sigma` values if you wish.

13.1.3.3 Simulation with uncertainty in all the parameters (by matrices)

If we assume these parameters came from 95 subjects with 8 observations apiece, the degrees of freedom for the `omega` matrix would be 95, and the degrees of freedom of the `sigma` matrix would be $95 \times 8 = 760$ because 95 items informed the `omega` matrix, and 760 items informed the `sigma` matrix.

```
Ribba2012 %>% # Use RxODE
  et(time.units="months") %>% # Pipe to a new event table
  et(amt=1, time=50, until=58, ii=1.5) %>% # Add dosing every 1.5 months
  et(0, 250, by=0.5) %>% # Add some sampling times (not required)
  rxSolve(nSub=3, nStud=3, omega=omega, sigma=lotri(prop.err ~ 0.05^2),
    dfSub=760, dfObs=95) %>% # Solve the simulation
  plot(pt, q, qp, pstar) # Plot it, plotting the variables of interest
```

Often in simulations we have a full covariance matrix for the fixed effect parameters. In this case, we do not have the matrix, but it could be specified by `thetaMat`.

While we do not have a full covariance matrix, we can have information about the diagonal elements of the covariance matrix from the model paper. These can be converted as follows:

```
rseVar <- function(est, rse){
  return(est*rse/100)^2
}

thetaMat <- lotri(tpt0 ~ rseVar(7.13,25),
  tq0 ~ rseVar(41.2,7),
  tlambdap ~ rseVar(0.121, 16),
  tkqpp ~ rseVar(0.0031, 35),
  tdeltaqp ~ rseVar(0.00867, 21),
  tgamma ~ rseVar(0.729, 37),
  tkde ~ rseVar(0.24, 33)
);

thetaMat

#>          tpt0   tq0  tlambdap   tkqpp  tdeltaqp  tgamma   tkde
#> tpt0      1.7825 0.000  0.00000  0.000000  0.0000000 0.00000 0.0000
#> tq0       0.0000 2.884  0.00000  0.000000  0.0000000 0.00000 0.0000
```

```
#> t1ambda 0.0000 0.000 0.01936 0.000000 0.0000000 0.00000 0.0000
#> tkqp 0.0000 0.000 0.00000 0.001085 0.0000000 0.00000 0.0000
#> tdeltaqp 0.0000 0.000 0.00000 0.000000 0.0018207 0.00000 0.0000
#> tgamma 0.0000 0.000 0.00000 0.000000 0.0000000 0.26973 0.0000
#> tkde 0.0000 0.000 0.00000 0.000000 0.0000000 0.00000 0.0792
```

Now we have a `thetaMat` to represent the uncertainty in the `theta` matrix, as well as the other pieces in the simulation. Typically you can put this information into your simulation with the `thetaMat` matrix.

With such large variability in `theta` it is easy to sample a negative rate constant, which does not make sense. For example:

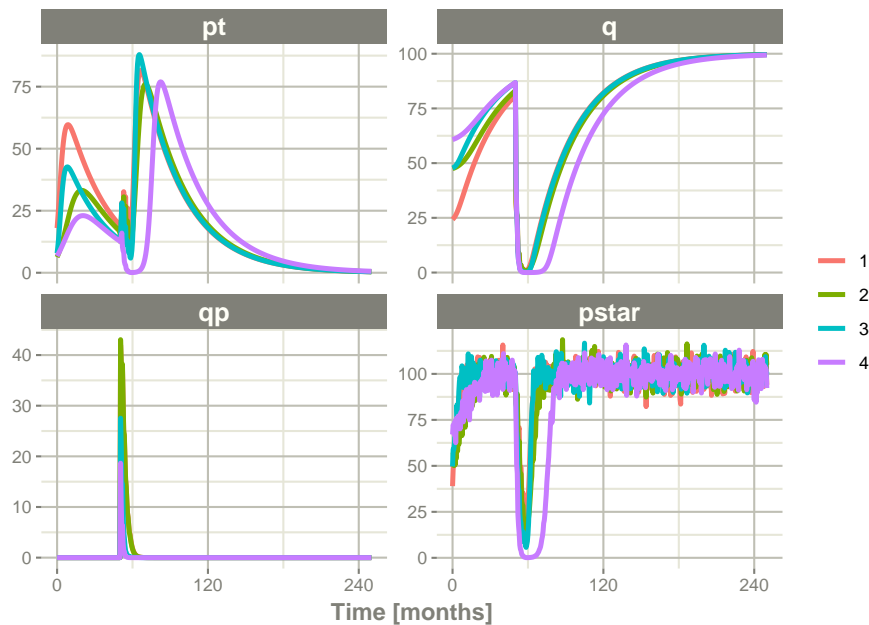

```
Ribba2012 %>% # Use RxODE
et(time.units="months") %>% # Pipe to a new event table
et(amt=1, time=50, until=58, ii=1.5) %>% # Add dosing every 1.5 months
et(0, 250, by=0.5) %>% # Add some sampling times (not required)
rxSolve(nSub=2, nStud=2, omega=omega, sigma=lotri(prop.err ~ 0.05^2),
thetaMat=thetaMat,
dfSub=760, dfObs=95) %>% # Solve the simulation
plot(pt, q, qp, pstar) # Plot it, plotting the variables of interest
```

```
#> unhandled error message: EE:[lsoda] 70000 steps taken before reaching tout
#> @([lsoda.c:750
#> Warning message:
#> In rxSolve_(object, .ctl, .nms, .extra, params, events, inits, setupOnly = .setupOnly,
#> Some ID(s) could not solve the ODEs correctly; These values are replaced with NA.
```

To correct these problems you simply need to use a truncated multivariate normal and specify the reasonable ranges for the parameters. For `theta` this is specified by `thetaLower` and `thetaUpper`. Similar parameters are there for the other matrices: `omegaLower`, `omegaUpper`, `sigmaLower` and `sigmaUpper`. These may be named vectors, one numeric value, or a numeric vector matching the number of parameters specified in the `thetaMat` matrix.

In this case the simulation simply has to be modified to have `thetaLower=0` to make sure all rates are positive:

```
Ribba2012 %>% # Use RxODE
et(time.units="months") %>% # Pipe to a new event table
et(amt=1, time=50, until=58, ii=1.5) %>% # Add dosing every 1.5 months
et(0, 250, by=0.5) %>% # Add some sampling times (not required)
rxSolve(nSub=2, nStud=2, omega=omega, sigma=lotri(prop.err ~ 0.05^2),
thetaMat=thetaMat,
thetaLower=0, # Make sure the rates are reasonable
dfSub=760, dfObs=95) %>% # Solve the simulation
plot(pt, q, qp, pstar) # Plot it, plotting the variables of interest
```

13.1.4 Summarizing the simulation output

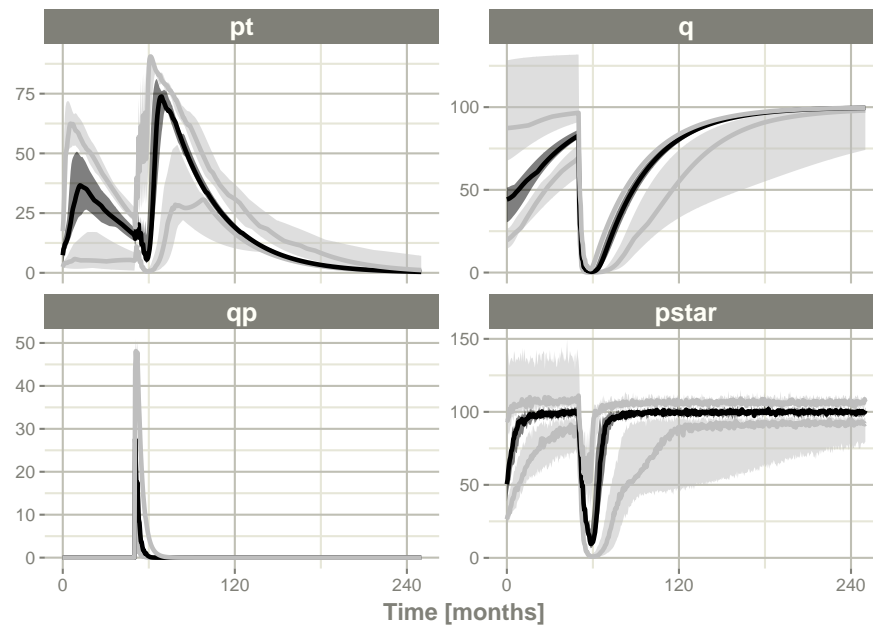

While it is easy to use `dplyr` and `data.table` to perform your own summary of simulations, `RxODE` also provides this ability by the `confint` function.

```
#### This takes a little more time; Most of the time is the summary
#### time.

sim0 <- Ribba2012 %>% # Use RxODE
  et(time.units="months") %>% # Pipe to a new event table
  et(amt=1, time=50, until=58, ii=1.5) %>% # Add dosing every 1.5 months
  et(0, 250, by=0.5) %>% # Add some sampling times (not required)
  rxSolve(nSub=10, nStud=10, omega=omega, sigma=lotri(prop.err ~ 0.05^2),
    thetaMat=thetaMat,
    thetaLower=0, # Make sure the rates are reasonable
    dfSub=760, dfObs=95) %>% # Solve the simulation
  confint(c("pt", "q", "qp", "pstar"), level=0.90); # Create Simulation intervals

#> summarizing data...done

sim0 %>% plot() # Plot the simulation intervals
```

13.1.4.1 Simulating from a data-frame of parameters

While the simulation from matrices can be very useful and a fast way to simulate information, sometimes you may want to simulate more complex scenarios. For instance, there may be some reason to believe that $tkde$ needs to be above $tlambdap$, therefore these need to be simulated more carefully. You can generate the data frame in whatever way you want. The internal method of simulating the new parameters is exported too.

```
library(dplyr)
pars <- rxInits(Ribba2012);
pars <- pars[regexr("(prop|eta)", names(pars)) == -1]
print(pars)
```

```
#>      k      tkde      tkpq      tkqpp tlambdap  tgamma tdeltaqp      tpt0
#> 1.00e+02 2.40e-01 2.95e-02 3.10e-03 1.21e-01 7.29e-01 8.67e-03 7.13e+00
#>      tq0
#> 4.12e+01
```

```
#### This is the exported method for simulation of Theta/Omega internally in RxODE
df <- rxSimThetaOmega(params=pars, omega=omega, dfSub=760,
                      thetaMat=thetaMat, thetaLower=0, nSub=60, nStud=60) %>%
  filter(tkde > tlambdap) %>% as.tbl()
```

```
#### You could also simulate more and bind them together to a data frame.
print(df)
```

```
#> # A tibble: 2,340 x 16
#>       k tkde tkpq tkqpp tlambda tgamma tdeltaqp tpt0 tq0 eta.pt0 eta.q0
#>   <dbl> <dbl> <dbl> <dbl>   <dbl> <dbl>   <dbl> <dbl> <dbl> <dbl> <dbl>

#> 10 100  2.83 0.0295 0.239   0.683  0.861   1.25  7.67 42.0 -0.495  0.161
#> # ... with 2,330 more rows, and 5 more variables: eta.lambda <dbl>,
#> #   eta.kqp <dbl>, eta.qpp <dbl>, eta.deltaqp <dbl>, eta.kde <dbl>
```

```
#### Quick check to make sure that all the parameters are OK.
all(df$tkde>df$tlambda)
```

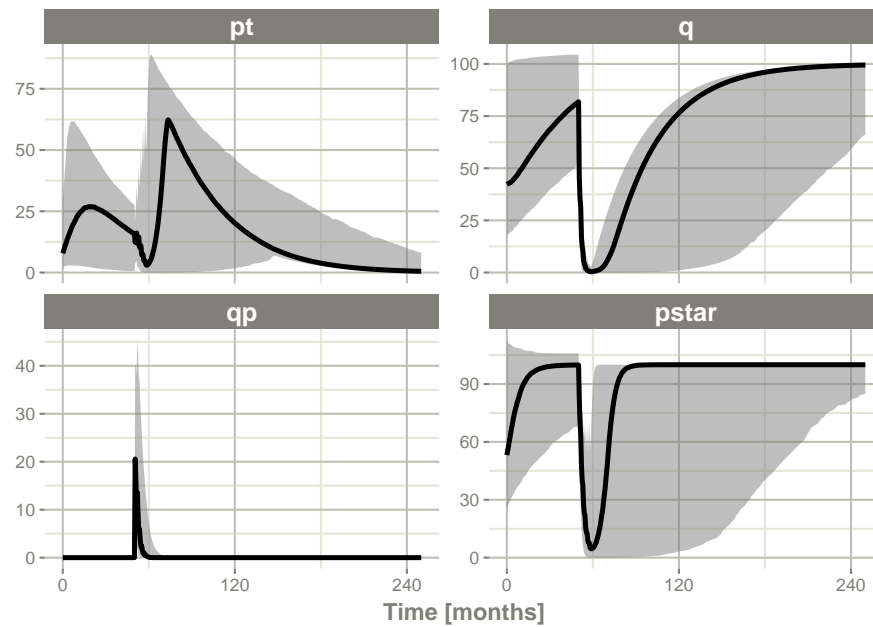

```
#> [1] TRUE
```

```
sim1 <- Ribba2012 %>% # Use RxODE
  et(time.units="months") %>% # Pipe to a new event table
  et(amt=1, time=50, until=58, ii=1.5) %>% # Add dosing every 1.5 months
  et(0, 250, by=0.5) %>% # Add some sampling times (not required)
  rxSolve(df)
#### Note this information loses information about which ID is in a
#### "study", so it summarizes the confidence intervals by dividing the
#### subjects into sqrt(#subjects) subjects and then summarizes the
#### confidence intervals
sim2 <- sim1 %>% confint(c("pt","q","qp","pstar"),level=0.90); # Create Simulation intervals
```

```
#> ! in order to put confidence bands around the intervals, you need at least 2500 simulations
```

```
#> summarizing data...done
```

```
save(sim2, file = file.path(system.file(package = "RxODE"), "pipeline-sim2.rds"), version = 2)
sim2 %>% plot()
```

13.2 Speeding up RxODE

13.2.1 Increasing RxODE speed by multi-subject parallel solving

RxODE originally developed as an ODE solver that allowed an ODE solve for a single subject. This flexibility is still supported.

The original code from the RxODE tutorial is below:

```
library(RxODE)

library(microbenchmark)
library(ggplot2)

mod1 <- RxODE({
  C2 = centr/V2;
  C3 = peri/V3;
  d/dt(depot) = -KA*depot;
  d/dt(centr) = KA*depot - CL*C2 - Q*C2 + Q*C3;
  d/dt(peri) = Q*C2 - Q*C3;
  d/dt(eff) = Kin - Kout*(1-C2/(EC50+C2))*eff;
  eff(0) = 1
})
```

```
#### Create an event table

ev <- et() %>%
  et(amt=10000, addl=9, ii=12) %>%
  et(time=120, amt=20000, addl=4, ii=24) %>%
  et(0:240) ## Add Sampling

nsub <- 100 # 100 sub-problems
sigma <- matrix(c(0.09,0.08,0.08,0.25),2,2) # IIV covariance matrix
mv <- rxRmvn(n=nsub, rep(0,2), sigma) # Sample from covariance matrix
CL <- 7*exp(mv[,1])
V2 <- 40*exp(mv[,2])
params.all <- cbind(KA=0.3, CL=CL, V2=V2, Q=10, V3=300,
                   Kin=0.2, Kout=0.2, EC50=8)
```

13.2.1.1 For Loop

The slowest way to code this is to use a for loop. In this example we will enclose it in a function to compare timing.

```
runFor <- function(){
  res <- NULL
  for (i in 1:nsub) {
    params <- params.all[i,]
    x <- mod1$solve(params, ev, cacheEvent=FALSE)
    ##Store results for effect compartment
    res <- cbind(res, x[, "eff"])
  }
  return(res)
}
```

13.2.1.2 Running with apply

In general for R, the apply types of functions perform better than a for loop, so the tutorial also suggests this speed enhancement

```
runSapply <- function(){
  res <- apply(params.all, 1, function(theta)
    mod1$run(theta, ev, cacheEvent=FALSE)[, "eff"])
}
```

13.2.1.3 Run using a single-threaded solve

You can also have RxODE solve all the subject simultaneously without collecting the results in R, using a single threaded solve.

The data output is slightly different here, but still gives the same information:

```
runSingleThread <- function(){
  solve(mod1, params.all, ev, cores=1, cacheEvent=FALSE)[,c("sim.id", "time", "eff")]
}
```

13.2.1.4 Run a 2 threaded solve

RxODE supports multi-threaded solves, so another option is to have 2 threads (called `cores` in the solve options, you can see the options in `rxControl()` or `rxSolve()`).

```
run2Thread <- function(){
  solve(mod1, params.all, ev, cores=2, cacheEvent=FALSE)[,c("sim.id", "time", "eff")]
}
```

13.2.1.5 Compare the times between all the methods

Now the moment of truth, the timings:

```
bench <- microbenchmark(runFor(), runSapply(), runSingleThread(), run2Thread())
print(bench)
```

```
#> Unit: milliseconds
#>      expr      min       lq      mean     median        uq       max
#> runFor() 156.50081 163.39227 172.54668 166.32387 176.26322 240.47595
#> runSapply() 157.99864 162.12564 172.66999 163.78468 170.95640 274.93771
#> runSingleThread() 22.68467 24.10475 24.78984 24.58824 25.04437 29.70837
#> run2Thread() 13.23406 13.82328 14.60440 14.04508 14.52565 24.09502
#> neval
#> 100
#> 100
#> 100
#> 100
```

```
autoplot(bench)
```

```
#> Coordinate system already present. Adding new coordinate system, which will replace
```

It is clear that the **largest** jump in performance when using the `solve` method and providing *all* the parameters to RxODE to solve without looping over each subject with either a `for` or a `sapply`. The number of cores/threads applied to the solve also plays a role in the solving.

We can explore the number of threads further with the following code:

```
runThread <- function(n){
  solve(mod1, params.all, ev, cores=n, cacheEvent=FALSE)[,c("sim.id", "time", "eff")]
}

bench <- eval(parse(text=sprintf("microbenchmark(%s)",
                                paste(paste0("runThread(", seq(1, 2 * rxCores()),"),"),
                                      collapse=","))))
print(bench)
```

```
#> Unit: milliseconds
#>      expr      min       lq      mean  median      uq      max neval
#> runThread(1) 24.034834 28.38872 30.91577 30.48492 33.18233 44.27491   100
#> runThread(2) 12.775390 16.37714 17.52786 16.81945 17.37160 32.63890   100
#> runThread(3) 10.461576 12.15869 13.38239 12.65254 13.21166 28.06261   100
#> runThread(4)  8.758859 10.24619 11.43938 10.62372 10.97831 24.89728   100
#> runThread(5) 11.544405 14.48137 15.47567 14.99451 15.67117 38.23430   100
#> runThread(6) 11.759385 13.07038 13.87341 13.43686 13.95978 37.97715   100
#> runThread(7) 11.096762 12.02211 12.67400 12.47018 12.94953 18.14013   100
```

```
#> runThread(8) 9.404845 11.33769 12.90951 11.65795 12.07957 42.31445 100
```

```
autoplot(bench)
```

```
#> Coordinate system already present. Adding new coordinate system, which will replace
```

There can be a suite spot in speed vs number of cores. The system type (mac, linux, windows and/or processor), complexity of the ODE solving and the number of subjects may affect this arbitrary number of threads. 4 threads is a good number to use without any prior knowledge because most systems these days have at least 4 threads (or 2 processors with 4 threads).

13.2.2 A real life example

Before some of the parallel solving was implemented, the fastest way to run RxODE was with `lapply`. This is how Rik Schoemaker created the data-set for `nlmixr` comparisons, but reduced to run faster automatic building of the pkgdown website.

```
library(RxODE)
library(data.table)
```

```
#>
#> Attaching package: 'data.table'
```

```
#> The following objects are masked from 'package:dplyr':
#>
#>     between, first, last
```

```
#Define the RxODE model
ode1 <- "
  d/dt(abs)      = -KA*abs;
  d/dt(centr)    =  KA*abs-(CL/V)*centr;
  C2=centr/V;
  "

#Create the RxODE simulation object
mod1 <- RxODE(model = ode1)

#Population parameter values on log-scale
params1 <- c(CL = log(4),
             V  = log(70),
             KA = log(1))

#make 10,000 subjects to sample from:
nsubg <- 300 # subjects per dose
doses <- c(10, 30, 60, 120)
nsub <- nsubg * length(doses)
#IIV of 30% for each parameter
omega <- diag(c(0.09, 0.09, 0.09)) # IIV covariance matrix
sigma <- 0.2
#Sample from the multivariate normal
set.seed(98176247)
library(MASS)
```

```
#>
#> Attaching package: 'MASS'
```

```
#> The following object is masked from 'package:dplyr':
#>
#>     select
```

```
#> The following object is masked from 'package:patchwork':
#>
#>     area
```

```
mv <-
  mvrnorm(nsub, rep(0, dim(omega)[1]), omega) # Sample from covariance matrix
#Combine population parameters with IIV
params.all <-
```

```

data.table(
  "ID" = seq(1:nsub),
  "CL" = exp(paramsl['CL'] + mv[, 1]),
  "V" = exp(paramsl['V'] + mv[, 2]),
  "KA" = exp(paramsl['KA'] + mv[, 3])
)
#set the doses (looping through the 4 doses)
params.all[, AMT := rep(100 * doses, nsubg)]

Startlapply <- Sys.time()

#Run the simulations using lapply for speed
s = lapply(1:nsub, function(i) {
  #selects the parameters associated with the subject to be simulated
  params <- params.all[i]
  #creates an eventTable with 7 doses every 24 hours
  ev <- eventTable()
  ev$add.dosing(
    dose = params$AMT,
    nbr.doses = 1,
    dosing.to = 1,
    rate = NULL,
    start.time = 0
  )
  #generates 4 random samples in a 24 hour period
  ev$add.sampling(c(0, sort(round(sample(runif(600, 0, 1440), 4) / 60, 2))))
  #runs the RxODE simulation
  x <- as.data.table(mod1$run(params, ev))
  #merges the parameters and ID number to the simulation output
  x[, names(params) := params]
})

#runs the entire sequence of 100 subjects and binds the results to the object res
res = as.data.table(do.call("rbind", s))

Stoplapply <- Sys.time()

print(Stoplapply - Startlapply)

```

```
#> Time difference of 5.110116 secs
```

By applying some of the new parallel solving concepts you can simply run the same simulation both with less code and faster:

```

rx <- RxODE({
  CL = log(4)
  V = log(70)
  KA = log(1)
  CL = exp(CL + eta.CL)
  V = exp(V + eta.V)
  KA = exp(KA + eta.KA)
  d/dt(abs) = -KA*abs;
  d/dt(centr) = KA*abs-(CL/V)*centr;
  C2=centr/V;
})

omega <- lotri(eta.CL ~ 0.09,
              eta.V ~ 0.09,
              eta.KA ~ 0.09)

doses <- c(10, 30, 60, 120)

startParallel <- Sys.time()
ev <- do.call("rbind",
  lapply(seq_along(doses), function(i){
    et() %>%
      et(amt=doses[i]) %>% # Add single dose
      et(0) %>% # Add 0 observation
    #### Generate 4 samples in 24 hour period
      et(lapply(1:4, function(...){c(0, 24)})) %>%
      et(id=seq(1, nsubg) + (i - 1) * nsubg) %>%
    #### Convert to data frame to skip sorting the data
    #### When binding the data together
      as.data.frame
  })))
#### To better compare, use the same output, that is data.table
res <- rxSolve(rx, ev, omega=omega, returnType="data.table")
endParallel <- Sys.time()
print(endParallel - startParallel)

```

```
#> Time difference of 0.09658575 secs
```

You can see a striking time difference between the two methods; A few things to keep in mind:

- RxODE use the thread-safe `jit` routines for simulation of eta values. Therefore the results are expected to be different (also the random samples are taken in a different order which would be different)

- This prior simulation was run in R 3.5, which has a different random number generator so the results in this simulation will be different from the actual nlmixr comparison when using the slower simulation.
- This speed comparison used `data.table`. RxODE uses `data.table` internally (when available) try to speed up sorting, so this would be different than installations where `data.table` is not installed. You can force RxODE to use `order()` when sorting by using `forderForceBase(TRUE)`. In this case there is little difference between the two, though in other examples `data.table`'s presence leads to a speed increase (and less likely it could lead to a slowdown).

13.2.2.1 Want more ways to run multi-subject simulations

The version since the tutorial has even more ways to run multi-subject simulations, including adding variability in sampling and dosing times with `et()` (see [RxODE events](#) for more information), ability to supply both an `omega` and `sigma` matrix as well as adding as a `thetaMat` to R to simulate with uncertainty in the `omega`, `sigma` and `theta` matrices; see [RxODE simulation vignette](#).

13.3 Integrating RxODE models in your package

13.3.1 Using Pre-compiled models in your packages

If you have a package and would like to include pre-compiled RxODE models in your package it is easy to create the package. You simply make the package with the `rxPkg()` command.

```
library(RxODE);
#### Now Create a model
idr <- RxODE({
  C2 = centr/V2;
  C3 = peri/V3;
  d/dt(depot) = -KA*depot;
  d/dt(centr) = KA*depot - CL*C2 - Q*C2 + Q*C3;
  d/dt(peri) = Q*C2 - Q*C3;
  d/dt(eff) = Kin - Kout*(1-C2/(EC50+C2))*eff;
})

#### You can specify as many models as you want to add

rxPkg(idr, package="myPackage"); ## Add the idr model to your package
```

This will:

- Add the model to your package; You can use the package data as `idr` once the package loads
- Add the right package requirements to the DESCRIPTION file. You will want to update this to describe the package and modify authors, license etc.
- Create skeleton model documentation files you can add to for your package documentation. In this case it would be the file `idr-doc.R` in your R directory
- Create a `configure` and `configure.win` script that removes and regenerates the `src` directory based on whatever version of RxODE this is compiled against. This should be modified if you plan to have your own compiled code, though this is not suggested.
- You can write your own R code in your package that interacts with the RxODE object so you can distribute shiny apps and similar things in the package context.

Once this is present you can add more models to your package by `rxUse()`. Simply compile the RxODE model in your package then add the model with `rxUse()`

```
rxUse(model)
```

Now both `model` and `idr` are in the model library. This will also create `model-doc.R` in your R directory so you can document this model.

You can then use `devtools` methods to install/test your model

```
devtools::load_all() # Load all the functions in the package
devtools::document() # Create package documentation
devtools::install() # Install package
devtools::check() # Check the package
devtools::build() # build the package so you can submit it to places like CRAN
```

13.3.2 Using Models in a already present package

To illustrate, lets start with a blank package

```
library(RxODE)
library(usethis)
pkgPath <- file.path(rxTempDir(), "MyRxModel")
create_package(pkgPath);
```

```

use_gpl3_license("Matt")
use_package("RxODE", "LinkingTo")
use_package("RxODE", "Depends") ## library(RxODE) on load; Can use imports instead.
use_roxygen_md()
##use_readme_md()
library(RxODE);
#### Now Create a model
idr <- RxODE({
  C2 = centr/V2;
  C3 = peri/V3;
  d/dt(depot) = -KA*depot;
  d/dt(centr) = KA*depot - CL*C2 - Q*C2 + Q*C3;
  d/dt(peri) = Q*C2 - Q*C3;
  d/dt(eff) = Kin - Kout*(1-C2/(EC50+C2))*eff;
});

rxUse(idr); ## Add the idr model to your package
rxUse(); # Update the compiled RxODE sources for all of your packages

```

The `rxUse()` will: - Create RxODE sources and move them into the package's `src/` directory. If there is only R source in the package, it will also finish off the directory with an `library-init.c` which registers all the RxODE models in the package for use in R. - Create stub R documentation for each of the models your are including in your package. You will be able to see the R documentation when loading your package by the standard `?` interface.

You will still need to: - Export at least one function. If you do not have a function that you wish to export, you can add a re-export of RxODE using roxygen as follows:

```

##' @importFrom RxODE RxODE
##' @export
RxODE::RxODE

```

If you want to use `Suggests` instead of `Depends` in your package, you way want to export all of RxODE's normal routines

```

##' @importFrom RxODE RxODE
##' @export
RxODE::RxODE

```

```

##' @importFrom RxODE et
##' @export
RxODE::et

```

```

##' @importFrom RxODE etRep

```

```
##' @export
RxODE::etRep

##' @importFrom RxODE etSeq
##' @export
RxODE::etSeq

##' @importFrom RxODE as.et
##' @export
RxODE::as.et

##' @importFrom RxODE eventTable
##' @export
RxODE::eventTable

##' @importFrom RxODE add.dosing
##' @export
RxODE::add.dosing

##' @importFrom RxODE add.sampling
##' @export
RxODE::add.sampling

##' @importFrom RxODE rxSolve
##' @export
RxODE::rxSolve

##' @importFrom RxODE rxControl
##' @export
RxODE::rxControl

##' @importFrom RxODE rxClean
##' @export
RxODE::rxClean

##' @importFrom RxODE rxUse
##' @export
RxODE::rxUse

##' @importFrom RxODE rxShiny
##' @export
RxODE::rxShiny

##' @importFrom RxODE genShinyApp.template
##' @export
RxODE::genShinyApp.template
```

```
##' @importFrom RxODE cvPost
##' @export
RxODE::cvPost

### This is actually from `magrittr` but allows less imports
##' @importFrom RxODE %>%
##' @export
RxODE::`%>%`
```

- You also need to instruct R to load the model library models included in the model's dll. This is done by:

```
### In this case `rxModels` is the package name
##' @useDynLib rxModels, .registration=TRUE
```

If this is a R package with RxODE models and you do not intend to add any other compiled sources (recommended), you can add the following configure scripts

```
#!/bin/sh
### This should be used for both configure and configure.win
echo "unlink('src', recursive=TRUE);RxODE::rxUse()" > build.R
${R_HOME}/bin/Rscript build.R
rm build.R
```

Depending on the check you may need a dummy autoconf script,

```
#### dummy autoconf script
#### It is saved to configure.ac
```

If you want to integrate with other sources in your Rcpp or C/Fortran based packages, you need to include `rxModels-compiled.h` and:

- Add the define macro `compiledModelCall` to the list of registered `.Call` functions.
- Register C interface to allow model solving by `R_init0_rxModels_RxODE_models()` (again `rxModels` would be replaced by your package name).

Once this is complete, you can compile/document by the standard methods:

```
devtools::load_all()
devtools::document()
devtools::install()
```

If you load the package with a new version of RxODE, the models will be recompiled when they are used.

However, if you want the models recompiled for the most recent version of RxODE, you simply need to call `rxUse()` again in the project directory followed by the standard methods for install/create a package.

```
devtools::load_all()
devtools::document()
devtools::install()
```

Note you do not have to include the RxODE code required to generate the model to regenerate the RxODE c-code in the `src` directory. As with all RxODE objects, a summary will show one way to recreate the same model.

An example of compiled models package can be found in the [rxModels](#) repository.

13.4 Stiff ODEs with Jacobian Specification

13.4.0.1 Stiff ODEs with Jacobian Specification

Occasionally, you may come across a [stiff differential equation](#), that is a differential equation that is numerically unstable and small variations in parameters cause different solutions to the ODEs. One way to tackle this is to choose a stiff-solver, or hybrid stiff solver (like the default LSODA). Typically this is enough. However exact Jacobian solutions may increase the stability of the ODE. (Note the Jacobian is the derivative of the ODE specification with respect to each variable). In RxODE you can specify the Jacobian with the `df(state)/dy(variable)= statement`. A classic ODE that has stiff properties under various conditions is the [Van der Pol](#) differential equations.

In RxODE these can be specified by the following:

```
library(RxODE)

Vtpol2 <- RxODE({
  d/dt(y) = dy
  d/dt(dy) = mu*(1-y^2)*dy - y
  ##### Jacobian
  df(y)/dy(dy) = 1
  df(dy)/dy(y) = -2*dy*mu*y - 1
  df(dy)/dy(dy) = mu*(1-y^2)
  ##### Initial conditions
  y(0) = 2
  dy(0) = 0
  ##### mu
  mu = 1 ## nonstiff; 10 moderately stiff; 1000 stiff
```

```

})

et <- eventTable();
et$add.sampling(seq(0, 10, length.out=200));
et$add.dosing(20, start.time=0);

s1 <- Vtpol2 %>% solve(et, method="lsoda")
print(s1)

```

```

#> ----- Solved RxODE object -----
#> -- Parameters ($params): -----
#> mu
#> 1
#> -- Initial Conditions ($inits): -----
#> y dy
#> 2 0
#> -- First part of data (object): -----
#> # A tibble: 200 x 3
#>   time      y      dy
#>   <dbl> <dbl> <dbl>
#> 1 0      22      0
#> 2 0.0503 22.0 -0.0456
#> 3 0.101 22.0 -0.0456
#> 4 0.151 22.0 -0.0456
#> 5 0.201 22.0 -0.0456
#> 6 0.251 22.0 -0.0456
#> # ... with 194 more rows
#> -----

```

While this is not stiff at $\mu=1$, $\mu=1000$ is a stiff system

```

s2 <- Vtpol2 %>% solve(c(mu=1000), et)
print(s2)

```

```

#> ----- Solved RxODE object -----
#> -- Parameters ($params): -----
#> mu
#> 1000
#> -- Initial Conditions ($inits): -----
#> y dy
#> 2 0
#> -- First part of data (object): -----
#> # A tibble: 200 x 3
#>   time      y      dy

```

```
#>      <dbl> <dbl>      <dbl>
#> 1 0      22      0
#> 2 0.0503 22.0 -0.0000455
#> 3 0.101  22.0 -0.0000455
#> 4 0.151  22.0 -0.0000455
#> 5 0.201  22.0 -0.0000455
#> 6 0.251  22.0 -0.0000455
#> # ... with 194 more rows
#> -----
```

While this is easy enough to do, it is a bit tedious. If you have RxODE setup appropriately, that is you have:

- **Python** installed in your system
- **sympy** installed in your system
- **SnakeCharmR** installed in R

You can use the computer algebra system sympy to calculate the Jacobian automatically.

This is done by the RxODE option `calcJac` option:

```
Vtpol <- RxODE({
  d/dt(y) = dy
  d/dt(dy) = mu*(1-y^2)*dy - y
##### Initial conditions
  y(0) = 2
  dy(0) = 0
##### mu
  mu = 1 ## nonstiff; 10 moderately stiff; 1000 stiff
}, calcJac=TRUE)
```

To see the generated model, you can use `rxCat()`:

```
> rxCat(Vtpol)
d/dt(y)=dy;
d/dt(dy)=mu*(1-y^2)*dy-y;
y(0)=2;
dy(0)=0;
mu=1;
df(y)/dy(y)=0;
df(dy)/dy(y)=-2*dy*mu*y-1;
df(y)/dy(dy)=1;
df(dy)/dy(dy)=mu*(-Rx_pow_di(y,2)+1);
```
